PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism ar Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

5844 ON THE TOPOGRAPHIC RELATIONSHIP BETWEEN THE DISTAL BRANCH OF LATARJET'S NERVE AND PROXIMAL DELIMITATION OF THE GASTRIC ANTRUM.

(Eng.) Brizzi, E.; Serantoni, C.; Ciani, P. A.; Fulignati, A.; Marinelli, R. (Universita di Firenze, Cattedra di Anatomia umana normale, Firenze, Italy). *Chir. Gastroenterol.* 11(3):297-298; 1977.

Histological investigations were carried out in 30 human stomachs to identify the boundary between the pyloric mucosa and that of the body and the fundus. This boundary was found to be situated on the lesser curvature, corresponding to the distal branch of Latarjet-Mitchell's nerve. Preoperative pH measurements confirmed these findings. In 20 stomachs, it was demonstrated that, on the lesser curvature, the mucosal boundary lies on a muscular ring formed by oblique fibers of gastric antral muscular membrane. The dissection of the distal branch of Latarjet-Mitchell's nerve showed the topographic relationship between this branch and the muscular ring. It is concluded that the distal branch of Latarjet-Mitchell's nerve topographically indicates the proximal delimitation of the gastric antrum.

5845 A SCANNING ELECTRON MICROSCOPIC STUDY OF NORMAL HUMAN OXYNTIC MUCOSA USING BLUNT DISSECTION AND FREEZE FRACTURE.

(Eng.) MacKercher, P. A.; Ivey, K. J.; Baskin, W. N.; Krause, W. J. (Harry S Truman Memorial Veterans Hosp., Columbia, MO). *Am. J. Dig. Dis.* 23(5):449-459; 1978.

To study the three-dimensional structure of the human gastric mucosa, biopsies from the fundic mucosa of healthy volunteers were examined by scanning electron microscopy following blunt dissection and freeze fracture. The mucosal surface exhibited a cobblestone appearance. With increased magnification, microvilli were demonstrated on the luminal surface of individual surface cells. Blunt dissection of the gastric mucosa revealed tubular gastric pits descending from the surface until they opened into branched tubular gastric glands. The gastric glands were irregular in outline due to the knoblike projections of individual parietal cells. The internal structure of the component cells also was examined with the scanning electron microscope following freeze fracture. Mucous granules were observed in the apical portion of surface epithelial cells. Lumina of parietal cell canaliculi were found to be continuous with the lumen of the gastric glands. Pepsinogen granules were seen throughout the chief cell cytoplasm. The blunt dissection-freeze fracture technique utilizing the scanning electron microscope allows, for the first time, a three-dimensional view of human gastric mucosa, including the gastric pits and glands as well as some of the internal architecture of component cells.

5846 IMMUNOHISTOCHEMICAL IDENTIFICATION AND LOCALIZATION OF PANCREATIC POLYPEPTIDE CELLS IN THE PANCREAS AND GASTROINTESTINAL TRACT OF THE HUMAN FETUS AND ADULT MAN.

(Eng.) Paulin, C.; Dubois, P. M. (Laboratoire d'Histologie et Embryologie, U.E.R. Medicale Lyon-Sud, B.P. n 12, 69600 Oullins, France). *Cell Tissue Res.* 188(2):251:257; 1978.

The evolution of pancreatic polypeptide (PP)-containing cells was studied in tissue from 5- to 24-week-old human fetuses, deceased premature infants, and normal adults. These cells were detected by using anti-bovine PP (BPP) serum in the pancreas and gastrointestinal tract specimens of the fetuses and premature infants and in biopsy-obtained specimens of the pancreas, antrum, and jejunum of adults with normal gastroduodenal endoscopy. Cell localization was established by studying the distribution of PP cells in comparison to the distribution of glucagon-, somatostatin-, and insulin-secreting cells. The first PP cells were seen in the pancreas at 10 weeks of gestation. They were located preferentially in the lower part of the head of the pancreas. The specificity of immunocytological reaction was ascertained by the inhibition of the reaction by preincubating the anti-BPP with BPP. Preincubation with somatostatin, gastrin, cholecystokinin, glucagon, or insulin did not modify the immunocytological reaction. Both the increased plasma levels of human PP and hyperplasia of PP cells previously reported in juvenile diabetes suggest a relation of PP to the physiopathology of diabetes.

5847 INTRAHEPATIC DISTRIBUTION OF NERVES IN THE RAT.

(Eng.) Reilly, F. D.; McCuskey, P. A.; McCuskey, R. S. (Coll. Medicine, Univ. Cincinnati, Cincinnati, OH 45267). *Anat. Rec.* 191(1):55-67; 1978.

As a result of the limited number of studies and lack of agreement on the intrahepatic distribution of nerves in the rat, a neurohistochemical and electron microscopic study of these nerves was initiated as part of an investigation of the neural component of mechanisms that regulate blood flow through the hepatic microvascular system in this species. Innervation was restricted primarily to vessels in the portal space and hilus. Both adrenergic and cholinergic fibers were observed in the adventitia of hepatic arteries, and to a lesser extent adjacent to portal veins. Some of the cholinergic fibers, however, were not contiguous with the vasculature. Near the hilus, many of these fibers were associated with ganglia, while, peripherally, some coursed into the immediately adjacent parenchyma where end bulbs abutted on hepatocytes. Ultrastructurally, scattered small nerves, devoid of neurolemma, were found contiguous with the portal lamina of hepatocytes. Nerve fibers deeper within the lobule were not seen, but numerous gap junctions were observed between contiguous hepatocytes. Central and sublobular hepatic veins lacked innervation, but adrenergic nerves were demonstrated in the walls of larger hepatic veins. Innervation of the biliary system was sparse. While nerves were interposed between vessels and bile ducts, such nerves tended to be associated more closely with the vasculature. Extreme care must be exercised in extrapolating results obtained from rodents, which have little hepatocellular innervation except by peripherally located cholinergic fibers, to primates, including humans, which have considerable innervation that is adrenergic rather than cholinergic.

5848 THE BIOCHEMICAL PHARMACOLOGY OF MUCUS. (Eng.) Parke, D. V.; Symons, A. M. (Dept. Biochemistry, Univ. Surrey, Guildford, Surrey, England). *Adv. Exp. Med. Biol.* 89:423-441; 1977.

ABSORPTION - EXCRETION - TRANSPORT

5855 ALTERATIONS IN RAT JEJUNAL PERMEABILITY TO A MACROMOLECULAR TRACER DURING A HYPEROSMOTIC LOAD. (Eng.) Cooper, M.; Teichberg, S.; Lifshitz, F. (North Shore Univ. Hosp., 300 Community Drive, Manhasset, NY 11030). *Lab. Invest.* 38(4):447-454; 1978.

The effects of intraluminal hyperosmolality on the intestinal permeability of a macromolecular tracer, horseradish peroxidase, was assessed in rats by light and electron microscopic cytochemistry to examine the role of hyperosmolality in the breakdown of the intestinal macromolecular barrier in some pathological conditions or stress situations. After 60 min of an intraluminal hypertonic perfusion of 600 mOsm mannitol, horseradish peroxidase was demonstrable in the intercellular spaces between adjacent absorptive epithelial cells of jejunal villi along the microvillar brush border, in numerous pinocytotic vesicles, in multivesicular bodies, as well as in large lysosomes. Horseradish peroxidase was frequently found extending from the luminal surface of the cell through the tight junctional region and into more basal portions of the intercellular space. In occasional cells, fragments of the interdigitating plasma membranes of two adjacent absorptive cells appeared to bud off into the cytoplasm of one cell. In contrast, after 60 min of isotonic perfusion, horseradish peroxidase was confined to the microvillar brush border, a few pinocytotic vesicles, and occasional multivesicular bodies. These experiments suggest that the passage of macromolecules across the jejunal epithelium of adult rats is enhanced under conditions of luminal hyperosmotic stress. This enhancement may be due to an alteration in the functional integrity of the tight junctional macromolecular barrier or to an increased rate of pinocytosis.

5856 THE USE OF THIRY-VELLA LOOP OF JEJUNUM TO STUDY THE INTESTINAL ABSORPTION OF CALCIUM AND INORGANIC PHOSPHATE IN THE CONSCIOUS PIG.

(Eng.) Fox, J.; Care, A. D.; Swaminathan, R. (Dept. Animal Physiology and Nutrition, Univ. Leeds, Leeds LS2 9JT, England). *Br. J. Nutr.* 39(3): 431-439; 1978.

Pigs prepared with Thiry-Vella jejunal loops were used to study intestinal calcium and inorganic phosphate absorption to investigate the mechanism of absorption. The loops were perfused daily for 6-8 hr with a nutrient solution, and absorption from the perfusate was measured. The technique employed minimized atrophy of the jejunal mucosa and enabled the measurement of hourly or daily changes in absorption rate of components of the luminal fluid. No differences were observed when polyethylene glycol (PEG, molecular weight 4,000), ^{14}C-PEG, or ^{51}Cr-EDTA were used as markers of net water movement. Increasing the concentration of Ca in the perfusate resulted in the demonstration of a two-component relationship between net absorption rate of Ca and intraluminal Ca concentration. An initial rapid absorption rate from 0 to 4 mM was found, and then a slower rate from approximately 5 mM upwards that did not saturate at the highest concentration tested (25 mM). Increasing the concentration of phosphate in the perfusion solution increased the net absorption of phosphate from that solution. Although a two-component system, similar to that for Ca, was not evident, net absorption of phosphate was not saturated at the highest concentration tested (50 mM). The absorption of Ca was unaffected by the presence of phosphate in the solution, but Ca (2-5 mM) enhanced phosphate absorption.

5857 THE INTESTINAL HANDLING OF CALCIUM BY THE RAT IN VIVO, AS AFFECTED BY CORTISOL. EFFECT OF DIETARY CALCIUM SUPPLEMENTS.

(Eng.) Ferretti, J. L.; Bazan, J. L.; Alloatti, D.; Puche, R. C. (Facultad de Medicina, Universidad Nacional de Rosario, Santa Fe 3100, 2000 Rosario, Argentina). *Calcif. Tissue Res.* 25(1):1-6; 1978.

The effects of cortisol on intestinal management of calcium and on related changes on bone metabolism were studied in five groups of 12 rats each fed a standard diet (0.8% Ca) and receiving 2, 6, 16, 32, or 128 mg/kg/day of cortisol hemisuccinate, s.c. After 16 days, intestinal absorption and excretion of Ca were measured with the aid of ^{45}Ca. True Ca absorption increased as a function of dose up to 16 mg/kg/day and remained high with the larger doses. Endogenous fecal Ca excretion increased exponentially as a function of the dose from 16 mg/kg/day onwards. Therefore, a dual effect was observed: (a) an increase in true Ca absorption at low cortisol doses (which increased net Ca absorption) and (b) an increase in endogenous fecal Ca excretion at high doses (which reduced net Ca absorption). In no case was a depression of true Ca absorption observed. Growth rate and food conversion efficiency were depressed only with a cortisol dose of 128 mg/kg/day. The urinary excretion of hydroxyproline, pyrophosphate, and aminopolysaccharides decreased with low doses and increased above normal levels with the highest dose. When animals treated with 128 mg/kg/day of cortisol were fed Ca-enriched diets (2.0 or 3.0% Ca), net Ca absorption improved ($p<0.01$). Simultaneously, growth rate and food conversion efficiency approached normal values. In these experiments, net absorption of Ca was found to be inversely related to urinary excretion of hydroxyproline. The urinary rate of excretion of hydroxyproline is suggested as an indicator of the effect of a Ca supplement on cortisol affected connective tissue turnover.

5858 ION TRANSPORT BY RABBIT COLON: II. UNIDIRECTIONAL SODIUM INFLUX AND THE EFFECTS OF AMPHOTERICIN B AND AMILORIDE.

(Eng.) Frizzell, R. A.; Turnheim, K. (Univ. Pittsburgh Sch. Medicine, Pittsburgh, PA 15261). *J. Membrane Biol.* 40(3):193-211; 1978.

To further examine the properties of Na and K transport in the rabbit colon, the unidirectional influx of Na from the mucosal solution into the epithelium was determined, and the effects of amiloride and amphotericin B on Na entry were evaluated. The unidirectional influx of Na from the mucosal solution into the epithelium of *in vitro* descending rabbit colon (J_{mc}^{Na}) determined under short-circuit conditions was found to be comprised of two components. One represents entry of Na into transporting epithelial cells and was abolished by amiloride (10^{-4} M), which also abolished Na absorption (J_{net}^{Na}). The other represented diffusional Na entry into paracellular pathways traversing the epithelium. In all instances, exposure of the mucosal surface to amphotericin B (15 μg/ml) increased tissue conductance and J_{net}^{Na} and elicited K secretion. Tissues showing a spontaneous short-circuit current (I_{sc}) of approximately 4 μEq/cm^2/hr did not respond to amphotericin B with increased I_{sc} and J_{net}^{Na}. However, in tissues characterized by a lower I_{sc} under control conditions, amphotericin B increased I_{sc} and J_{net}^{Na} to approximately 4 μEq/cm^2/hr. These findings suggest that amphotericin increases J_{net}^{Na} and elicits K secretion by disrupting the normal perm-selectivity of the mucosal membrane. Under these conditions the extrusion of Na from cell-to-serosal solution becomes the rate limiting step in transepithelial Na transport. Finally, a close correlation between J_{mc}^{Na} and J_{net}^{Na} was observed when the rate of Na absorption varied either spontaneously or experimentally with amiloride, suggesting that the backflux of Na from cell-to-mucosal solution is undetectably small.

5859 SODIUM TRANSPORT BY ISOLATED BULLFROG SMALL INTESTINE: EFFECT OF PROSTAGLANDIN

E_1. (Eng.) Gerencser, G. A.; Tyler, T.; Cassin, S. (Univ. Florida, Coll. Medicine, Gainesville, FL). *Biochim. Biophys. Acta* 509(1):159-169; 1978.

Prostaglandin E_1 (PGE_1, 446 μM) was added to the serosal and mucosal media of isolated short-circuited bullfrog small intestine to investigate the mechanism of its stimulatory action on sodium secretion in the small intestine. The addition of PGE_1 to the serosal medium elicited small increases in transmural potential difference (PD) and short-circuit current (SCC), while addition of PGE_1 to the mucosal medium caused no change in the electrical parameters. The addition of 100 μM indomethacin to the mucosal medium inhibited both PD and SCC with a resultant increase in steady-state tissue resistance. In the presence of mucosal 100 μM indomethacin, serosal PGE_1 (60 μM) markedly stimulated transmural PD and SCC with a resultant decrease in steady-state tissue resistance. Serosal arachidonic acid (330 μM) stimulated transmural PD and SCC and this effect was abolished by the addition of 100 μM indomethacin to the mucosal medium. Serosal PGE_1 (60 μM) only stimulated the mucosa→serosa unidirectional flux of sodium. These results strongly suggest that the PGE_1 action is mediated either via a series of metabolic reactions that possibly increase the permeability of the mucosal membrane to sodium or via direct stimulation of rheogenic sodium pump activity.

5860 Na^+ TRANSPORT BY MAMMALIAN STOMACH. (Eng.) Machen, T. E.; Silen, W.; Forte, J. G. (Dept. Physiology-Anatomy, Univ. California, Berkeley, CA 94720). *Am. J. Physiol.* 234(3):E228-E235; 1978.

Gastric mucosas from newborn pigs (0-20 days) and rabbits (0-20 days) were used for an *in vitro* investigation of active Na^+ transport during resting (no HCl secretion) conditions. As measured with $^{22}Na^+$, these tissues were found to actively absorb Na^+ from the mucosal-to-serosal (m-to-s) bathing solution during both open-circuit and short-circuit current (I_{sc}) conditions. In the nonsecreting state, net Na^+ transport accounted for 40-60% of I_{sc}. The remaining current was provided by net s-to-m flux of Cl^-. Amiloride (2-5 x 10^{-5} M) in the mucosal solution abolished this active Na^+ transport by inhibiting m-to-s fluxes of Na^+ (J^{Na}_{ms}). *In vivo-in vitro* experiments showed that active Na^+ transport was a normal function of the resting mammalian stomach. Decreasing the pH of the mucosal solution to below pH 5 reversibly decreased the current-generating capability of the tissue. Pretreatment of the tissue with amiloride abolished this pH effect. The implication is that the low pH affects the Na^+-entry step into cells. "Titration curves" of current versus pH had an apparent pK of approximately 4.0. Ouabain and K^+-free solutions both caused decreases in active Na^+ and Cl^- current. Calculations indicated that a shunt may account for only a small (<30%) percentage of total transepithelial conductance.

5861 GLUCOSE AND CATION TRANSPORT IN RAT JEJUNUM, ILEUM AND COLON IN VIVO: CONTROL EXPERIMENTS, AND EFFECT OF CATIONIC SURFACTANT. (Eng.) Sund, R. B. (Inst. Pharmacy, Univ. Oslo, P.O. Box 1068, Blindern, Norway). *Acta Pharmacol. Toxicol. (Kbh.)* 42(2):117-124; 1978.

To investigate the mechanism by which surfactants affect intestinal glucose transport, osmotically balanced solutions of glucose (0.5-300 mM) and sodium chloride, containing cetrimonium bromide (cetrimide, 0.8-4.1 mM), were instilled into the jejunum, ileum, and colon of anesthetized rats. Net transport of glucose, sodium, and potassium was studied by their disappearance from or accumulation into the intestinal lumen during 15 min of incubation. Cetrimide caused the following shifts in normal jejunal and ileal glucose absorption: at low luminal glucose levels, absorption was strongly depressed and may be converted to net secretion. At intermediate levels, inhibition was less pronounced, and at high luminal glucose levels, absorption was enhanced. Similar changes were seen in the colon. Furthermore, cetrimide caused a threefold change in the regression lines relating net sodium fluxes to the initial sodium concentration. The lines became steeper, the correlation was improved, and the sodium concentration value corresponding to zero net transport was elevated. Net potassium secretion was increased. These changes are all consistent wit the view that surfactants cause an increase in passive epithelial permeability. Quantitatively, the effect of cetrimide increased with localization in the order colon>ileum>jejunum. Benzalkonium chlorid (0.5-1.7 mM) was tested in the ileum only, and cause similar effects.

5862 EFFECT OF DIESTER AND DIETHER PHOSPHATIDYLCHOLINE ON INTESTINAL ABSORPTION OF NEUTRAL ACIDIC STEROLS. (Eng.) O'Connor, P. J.; Loiudice, T. A.; Bochenek, W.; Rodgers, J. B. (Albany Medical Coll., Albany, NY 12208). *Am. J. Dig. Dis.* 23(4):316-320; 1978.

To determine whether the delay in cholesterol absorption noted when phosphatidylcholine is infused intraduodenally with dihydroxy bile salt plus natural phospholipid might be mediated via a delay in digestion and subsequent absorption of the phospholipid, the effects of nondigestible diether phosphatidylcholine on intestinal cholesterol and dihydroxy and trihydroxy conjugated bile salt absorption were studied in bile fistula rats using radioactive substrates. No inhibition of absorptio of either dihydroxy or trihydroxy bile salts was observed. Nondigestible phospholipid did, however, significantly inhibit cholesterol absorption ($p<0.0$ when infused with taurocholate [TC]; $p<0.05$ with taurochenodeoxycholate [TCD]). Under control conditions with natural phosphatidylcholine in the intestinal perfusate, cholesterol absorption was significantly greater ($p<0.01$) when infused with TC as compared to results obtained after infusion with TCD. Studies were repeated using radioactive rat liver phosphatidylcholine to determine whether the observed decrease in cholesterol absorption could be correlated with a decrease in digestion and absorption of rat liver phosphatidylcholine. No evidence was found for decreased absorption of his phospholipid when given with TCD. It is concluded that less cholesterol is absorbed in the resence of TCD than of TC, but the mechanism for his difference remains unexplained.

5863 VITAMIN D-3 INTESTINAL ABSORPTION IN VIVO: INFLUENCE OF FATTY ACIDS, BILE SALTS, AND ERFUSATE pH ON ABSORPTION. (Eng.) Hollander, D.; uralidhara, K. S.; Zimmerman, A. (Scott Hall asic Medical Sciences, 540 E. Canfield, Detroit, I 48201). *Gut* 19(4):267-272; 1978.

ntestinal vitamin D-3 absorption in physiological oncentrations was studied in the live unanesthetized rat, and the effects of fatty acids, bile alts, and perfusate pH were investigated. In both he jejunum and the ileum, a linear relation as found between the absorption rate of the vitamin nd its intraluminal concentration. Increasing the odium taurocholate concentration in the perfusate bove 5 mM did not change ileal absorption rate but id decrease jejunal absorption rate. The vitamin's bsorption rate was raised by increases in either the hydrogen ion concentration or the perfusate's low rate. Addition of 2.5 mM fatty acids of varying chain length and degrees of saturation resulted in a decrease in the rate of vitamin D-3 absorption. These experiments indicate that vitamin D-3 absorption *in vivo* is mediated by passive diffusion. The rate of absorption of the vitamin is influenced by the composition of the perfusate and the thickness of the unstirred layer.

MOTILITY

5871 ESOPHAGEAL GANGLIA AND SMOOTH MUSCLE IN THE ELDERLY. (Eng.) Eckardt, V. F.; LeCompte, P. M. (I. Medizinische Universitatsklinik Mainz, 65 Mainz, Langenbeckstrasse 1, W. Germany). *Am. J. Dig. Dis.* 23(5):443-448; 1978.

To study the etiology of esophageal motor dysfunction in elderly persons, the histology of Auerbach's plexus and esophageal smooth muscle was examined in autopsy material from 9 young (29 ± 2.2 yr) and 15 elderly (77.4 ± 2.8 yr) subjects. There was a significant decrease in ganglion cells (1,685 ± 115.9/cm^2) in elderly subjects when compared to young controls (2,253 ± 216.9/cm^2, $p<0.05$). Lymphocytic infiltration of Auerbach's plexus was commonly observed in both groups of patients, but heavy lymphocytic infiltration was slightly more common in elderly subjects. No difference was found in thickness of esophageal smooth muscle between young and old subjects. It is concluded that diminution of ganglion cells rather than smooth muscle atrophy may explain the frequent occurrence of esophageal motor dysfunction in elderly persons.

5872 ELECTRICAL ACTIVITY OF THE OPOSSUM LOWER ESOPHAGEAL SPHINCTER IN VIVO: ITS ROLE IN THE BASAL SPHINCTER PRESSURE.

(Eng.) Asoh, R.; Goyal, R. K. (Univ. Texas Health Science Center, 5323 Harry Hines Blvd., Dallas, TX 57235). *Gastroenterology* 74(5, Part 1):835-840; 1978.

Studies were performed in anesthetized opossums to investigate the electrical control of the lower esophageal sphincter. The stomach and lower end of the esophagus were immobilized on a specially prepared stage to eliminate movement artifacts. Extracellular electrical activity was recorded with bipolar needle electrodes. The sphincter pressure was measured with a continuously perfused catheter system. The lower esophageal sphincter showed continuous spike activity with or without phasic variations in their occurrence. The usual frequency of the spikes was 20-50/min, and their mean duration was 81.2 ± 8.9 msec. The spike potentials ceased with esophageal distention, which also caused a fall in the sphincter pressure. The spikes were abolished by isoproterenol (2.5 μg/kg, i.v.) and they increased with bethanechol (20 μg/kg, i.v.). Correlation of the spike activity with the pressure revealed that the sphincter pressure was higher when the spike potentials were present, but a major part of the pressure existed in the absence of any spike activity. These studies show that (1) the opossum lower esophageal sphincter is characterized by continuous spike potentials and (2) the major fraction of the basal pressure is, however, independent of the spike potentials.

5873 MOTOR INNERVATION OF STRIATED OESOPHAGEAL MUSCLE. PART 2. CHARACTERISTICS OF THE OESOPHAGOMOTOR FIBRES IN THE RAT STUDIED BY IMPLANTING THE VAGUS NERVE INTO A SKELETAL MUSCLE.

(Eng.) Gruber, H. (II. Anatomisches Institut der Universitat Wien, A-1090 Vienna, Austria). *J. Neurol. Sci.* 36(2):171-186; 1978.

In 12 rats, the right vagus nerve distal to its recurrent laryngeal branch was implanted into the inferior segment of the denervated sternohyoid muscle to determine whether the esophagomotor fibers, prior to joining the myenteric plexus, can form functionally adequate neuromuscular junctions. One month after implantation, the first signs of neuromuscular transmission at the vagal motor endings could be recorded. Two months after implantation, the reinnervated muscles showed vigorous contractions on electrical stimulation of the vagus nerve. During the performance of propulsive waves of the esophagus, the implanted vagus nerve caused clonic to tetanic contractions of the sternohyoid muscle, thus proving the esophagomotor genesis of the reinnervating nerve fibers. In addition, the vagus-innervated motor end-plates were shown to exhibit the same ultrastructural peculiarities as the original neuromuscular junctions of the esophagus. In sections stained for cholinesterase, it was demonstrated that the esophagomotor fibers had preferentially reinnervated the denervated motor end-plates. In many instances, the subneural apparatus was not completely covered by the vagal axon terminals. Newly formed, ectopic vagal motor endings were few in number and confined to muscle fibers immediately adjacent to the site of nerve-implantation. Six months after implantation, some of the vagal motor endings showed signs of degeneration. As in the esophagus, the reinnervating esophagomotor fibers proved to be unmyelinated, sometimes forming a plexus-like intramuscular network before terminating at motor end-plates. Myelinated vagal nerve fibers were also observed running between the skeletal muscle fibers, but they did not establish any demonstrable form of neuromuscular contacts. It is concluded that in the rat the myelinated fibers of the esophageal nerves are afferent, whereas the esophagomotor fibers, although supplying striated muscle, are unmyelinated.

5874 THE EFFECT OF ATROPINE ON THE LOWER ESOPHAGEAL SPHINCTER IN LATE PREGNANCY.

(Eng.) Dow, T. G. B.; Brock-Utne, J. G.; Rubin, J.; Welman, S.; Dimopoulos, G. E.; Moshal, M. G. (Dept. Obstetrics and Gynecology, Univ. Natal, South Africa). *Obstet. Gynecol.* 51(4):426-430; 1978.

Intraluminal pressure and pH changes at the gastroesophageal region before and after atropine administration were studied in pregnant and nonpregnant women, because atropine is used prior to caesarean section and could possibly lead to esophageal reflux, regurgitation, and aspiration. Eight nonpregnant women, 10 pregnant women with heartburn, and 10 pregnant women without heartburn were studied. Each patient was tested under resting conditions and after the i.v. injection of atropine (0.6 mg). In both groups of pregnant patients, the intragastric pressure was higher than that of the nonpregnant subjects ($p<0.01$ before atropine, $p<0.005$ after atropine). The stomach to lower esophageal sphincter pressure (LESP) gradient under resting conditions was lowest in the pregnant patients with heartburn. After the administration of atropine, a fall in the LESP occurred in all three groups of patients and was most profound in the nonpregnant subjects (9.6 cm H_2O, $p<0.02$) and in the pregnant patients without heartburn (17.1 cm H_2O, $p<0.05$). These changes and the pH recordings of the lower esophagus indicate the adverse effect that atropine has on the competency of the LESP both in pregnancy and in the nonpregnant state. Atropine should therefore be used with caution as a premedicant and preferably combined with metoclopramide.

5875 EFFECT OF THORACIC VAGOTOMY AND VAGAL STIMULATION ON ESOPHAGEAL FUNCTION.

(Eng.) Kravitz, J. J.; Snape, W. J., Jr.; Cohen, S. (Univ. Pennsylvania Hosp., Philadelphia, PA 19104). *Am. J. Physiol.* 234(4):E359-E364; 1978.

To gain information on esophageal innervation by the thoracic portion of the vagus nerves, the effect of thoracic vagotomy and thoracic vagal stimulation upon esophageal peristalsis and lower esophageal sphincter (LES) function was studied in the opossum. The thoracic portion of the vagus nerve was sectioned in the upper or lower thorax. Bilateral, but not unilateral, thoracic vagotomy above the level of the heart abolished peristalsis and LES relaxation in response to swallowing or cervical vagal electrical stimulation. Thoracic vagotomy at the level of the ventricle or below did not alter either peristalsis or LES relaxation during swallowing or cervical vagal stimulation. Secondary peristalsis and its associated LES relaxation was unaltered by thoracic vagotomy at any level. Electrical stimulation of the distal end of the upper thoracic vagus elicited both peristalsis and LES relaxation. Electrical stimulation of the distal end of the lower thoracic vagus, as well as stimulation of the vagal branches to the terminal esophagus, gave only LES relaxation. These studies suggest that (a) the major extrinsic vagal innervation mediating primary peristalsis terminates in the upper portion of the esophagus, whereas the vagal innervation mediating LES relaxation responses are present throughout the length of the esophagus, and (b) secondary peristalsis and its associated LES relaxation occurs independent of extrinsic vagal innervation.

5876 MYOELECTRICAL AND MECHANICAL ACTIVITY OF ISOLATED CANINE STOMACH PERFUSED IN VITRO WITH FLUOROCARBON: ROLE OF GLUCOSE, PHOSPHATE, CALCIUM AND STRONTIUM IN THE PERFUSATE.

(Eng.) Kowalewski, K.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton T6G 2N8, Canada). *Pharmacology* 16(5):247-258; 1978.

Myoelectrical and mechanical activities were recorded from whole isolated canine stomachs perfused intravascularly with fluorocarbon emulsion, oxygenated *in vitro*, to assess the use of this bloodless artificial perfusate in preserving the stomach during secretory and motility studies. The perfusate was composed of an oxygen carrier (liquid fluorocarbon) emulsified with a surfactant and added to a simulated physiological solution. Bipolar electrodes and a strain gauge were used for recordings. Stomachs perfused for 5 hr displayed normal electrical and mechanical activities (i.e., identical with those observed under *in vivo* conditions or during perfusion with homologous blood). Normal responses to electrical stimulation of a vagus nerve branch or to the intraarterial injection of 10 μg methacholine or 5 μg pentagastrin were also observed. These functions of smooth muscles were not altered when glucose-free or glucose- and phosphate-free perfusate were used. In calcium-free perfusate, electrical and mechanical activities were absent, and no responses to stimulants used were recorded. When calcium was added to the perfusate, these functions were restored to normal. Strontium was found to be an adequate substitute for calcium in fluorocarbon perfusate. Gastric secretions were alkaline and contained fluorocarbon emulsion. These studies demonstrate that myoelectrical and mechanical activity of the isolated canine stomach is well preserved during perfusion with fluorocarbon emulsion.

5877 CHOLECYSTOKININ INHIBITS GASTRIC EMPTYING BY ACTING ON BOTH PROXIMAL STOMACH AND PYLORUS.

(Eng.) Yamagishi, T.; Debas, H. T. (Dept. Surgery, Univ. British Columbia, Vancouver, British Columbia, V5Z 1L5, Canada). *Am. J. Physiol.* 234(4): E375-E378; 1978.

The relative importance of the ability of cholecystokinin to relax the proximal stomach and to contract the pyloric sphincter in its inhibitory effect on gastric emptying was investigated in dogs by studying the effectiveness of the C-terminal octapeptide of cholecystokinin (OP-CCK) to inhibit the emptying of a liquid meal (300 ml saline) before and after operations that either remove or destroy the pyloric mechanism (antrectomy and pyloroplasty), or lead to loss of accommodation of the proximal stomach (vagotomy), and after both vagotomy and antrectomy, and vagotomy and pyloroplasty. OP-CCK caused dose-related (32-250 ng/kg/hr) inhibition of gastric emptying in the intact dog. After either pyloroplasty or antrectomy the effectiveness of low (32-125 ng/kg/hr) but not of high doses of OP-CCK (250-500 ng/kg/hr) was lost. After vagotomy, OP-CCK at any dose was ineffective. The findings suggest that cholecystokinin inhibits gastric emptying by acting both on the pylorus and on the proximal stomach.

5878 EFFECTS OF DOMPERIDONE (R 33812) ON THE MOTOR FUNCTION OF THE STOMACH AND SMALL INTESTINE: A DOUBLE-BLIND EVALUATION.

(Eng.) Baeyens, R.; Reyntjens, A.; Van de Velde, E. (Janssen Pharmaceutica N. V., B-2340 Beerse, Belgium). *Arzneim. Forsch.* 28(4):682-686; 1978.

To investigate the mechanism of the new antiemetic agent, domperidone, the effect of i.v. domperidone on the motor function of the stomach and small intestine was evaluated in three consecutive controlled studies using different treatment regimens. Two hundred one patients were referred to the radiodiagnostic department for a barium meal with a follow-through examination. In study A, 48 patients received either domperidone (8 mg) or a placebo, given simultaneously with the barium meal. In study B, the same treatment was used in 50 patients, but the injections were given 30 min before the barium. Twenty-four other patients received metoclopramide (10 mg) instead of domperidone or a placebo. In study C, the domperidone injections were given 15 min after the barium meal in 49 patients. Thirty other patients received either the placebo (10), domperidone (10), or metoclopramide (10). Peristaltic activity of the antrum, gastric emptying, and small bowel transit time were evaluated after the ingestion of the barium meal, and before and/or after the drug injections. Antral peristalsis was more activated with domperidone and metoclopramide than with placebo, but this effect was seen only when domperidone was administered either before ($p<0.05$) or after ($p<0.001$) the administration of the barium meal. Regardless of the time of administration, gastric emptying was accelerated by domperidone ($p<0.05$) and by metoclopramide. Bowel transit was accelerated by both domperidone and metoclopramide ($p<0.01$). Both domperidone and metoclopramide improved motor function in the proximal part of the gastrointestinal tract. It is concluded that domperidone synchronizes gastrointestinal motor function due to a more protractive activity, whereas metoclopramide merely acts as a "hurrying" agent.

5879 GASTRIC EMPTYING IN THE CAT IN RESPONSE TO HYPERTONIC SOLUTIONS AND TRYPTOPHAN. (Eng.) Cooke, A. R. (Kansas Univ. Medical Center, Rainbow Blvd. at 39 St., Kansas City, KS 66103). *Am. J. Dig. Dis.* 23(4):312-315; 1978.

To study possible species differences in the response of gastric emptying to hypertonic sugar and amino acid solutions and tryptophan, gastric emptying studies were carried out in 10 cats and 4 dogs, each having a gastric fistula. Test meals of 50 ml (cats) or 300 ml (dogs) containing phenol red as a nonabsorbable marker were instilled into the stomach via the gastric fistula and were drained by gravity 25-30 min later. The test meals were water, hypertonic solutions (250-1,000 mOsm/kg) of casein hydrolysate, D-glucose, mannitol, glycine, L-alanine, D-alanine, β-alanine, L- and D-tryptophan, and L-phenylalanine in concentrations (osmolalities) ranging from 5 to 100 mM. In the cats, gastric emptying was slowed with increasing osmolality of the test solution; glucose and mannitol were equipotent but much less effective than glycine or casein hydrolysate. This difference in potencies was not found for these substances in the dogs. Gastric emptying was inhibited by tryptophan in the cats and was stereospecific, only the L form being effective. This inhibition was not due to the effect of tryptophan on acid secretion. Stereospecificity was not found for the osmoreceptor. Combining L-tryptophan with another neutral amino acid (L-alanine) inhibited the effect of tryptophan. Phenylalanine in concentrations up to 80 mM had no effect on gastric emptying in the cats. These studies indicate differences between cats and dogs in response to osmotic agents and also show that, like the dog, the cat has a tryptophan receptor.

5880 SMALL-INTESTINAL TRANSIT DURING TOTAL PARENTERAL NUTRITION IN THE RAT. (Eng.) Weisbrodt, N. W.; Badial-Aceves, F.; Copeland, E. M.; Dudrick, S. J.; Castro, G. A. (Univ. Texas Medical Sch., P.O. Box 20708, 6400 W. Cullen, Houston, TX 77030). *Am. J. Dig. Dis.* 23(4):365-369; 1978.

The hypothesis that alterations in small bowel motility are associated with total parenteral nutrition (TPN) was tested. Motility, as reflected by intestinal transit, was studied in rats maintained by TPN for 7-10 days and compared with that of rats fed a p.o. diet isocaloric with the i.v.-administered solution. Transit was measured by injecting radioactively labeled chromium ($Na_2{}^{51}CrO_4$) into the duodenum via permanently implanted catheters. The animals were killed 15 min after injecting the label, and the linear distribution of the isotope in the gut was determined. The leading edge of radioactivity traversed 75-87% (95% confidence limit) of the gut length in p.o.-fed rats and 83-97% in rats on TPN. The difference between the average position of these fronts for the two groups was not statistically significant. In addition, the regression of percentage radioactivity traversi or present in a given segment on gut length yielded a slope with 95% confidence limits of -10.48 to -15.02 for p.o.-fed control rats and -9.83 to -12.8 for rats on TPN ($p>0.05$). These results support the conclusion that factors that regulate small bowel motility are not altered significantly by TPN during the time that other functional and structura changes reportedly occur.

5881 THE SACRAL PARASYMPATHETIC REFLEX PATHWAY REGULATING COLONIC MOTILITY AND DEFAECATION IN THE CAT. (Eng.) De Groat, W. C.; Krier, J. (Medical Sch., Univ. Pittsburgh, Pittsburgh, PA 15261). *J. Physiol. (Lond.)* 276:481-500; 1978.

To examine the role of the sacral parasympathetic pathway to the colon in the regulation of colonic motility, intestinal motility and the efferent firing in postganglionic fibers on the serosal surface of the mid-distal colon were measured simultaneously in cats. Increases in efferent firing were noted during the occurrence of spontaneous propulsive activity (tonic pressure waves) or segmental contractions (slow rhythmic pressure waves). The neural discharge was not altered by transection of the lumbar sympathetic innervation to the colon but was blocked by interruption of the sacral parasympathetic outflow. Electrical stimulation of pelvic nerve afferents arising in the colon or distention of the colon or rectum evoked reflex increases in efferent firing and sustained propulsive contractions that were associated with defecation. Both responses were abolished by transection of the pelvic nerves or sacral dorsal roots. Electrical stimulation of colonic afferent fibers also evoked synchronous reflex discharges in colonic efferents at latencies ranging from 180 to 300 msec. The discharges were enhanced during propulsive contractions, and abolished by transection of the pelvic nerves but not altered by transection of the lumbar sympathetic nerves. Sacral reflexes were present in cats with an intact spinal cord and in chronic spinal animals (transection at thoracic vertebrae 10-12). The reflexes recovered within minutes to several hours after acute transection of the spinal cord. Electrophysiological measurements indicated that the sacral reflexes to the large intestine were mediated by nonmyelinated afferent and preganglionic efferent fibers. The central delay for the reflex was estimated to be 45-60 msec. It is concluded that the sacral parasympathetic reflexes to the large intestine are mediated via a spinal pathway and have an essential role in the initiation of propulsive activity during defecation.

5882 SPHINCTERIC MECHANISM OF THE MAIN PANCREATIC DUCT IN THE DOG: AN EXPERIMENTAL MODEL OF THE ISOLATED SPHINCTERIC PREPARATION. (Eng.) Sankaran, H.; FitzGerald, O.; McGeeney, K. F. (Dept. Medicine and Therapeutics, Univ. Coll., Dublin, Ireland). *Digestion* 17(3):221-228; 1978.

An *in vitro* experimental model of the sphincter at the lower end of the main pancreatic duct was developed in dogs. This model, employing a drop counter to measure the drop rate, monitors the perfusion rate of Tyrode through the sphincter. Acetylcholine (ACh; 25, 50, 100, and 200 μg), employed to establish the sensitivity and viability of the isolated sphincter, produced a contraction of the sphincter that was concentration-response related (the drop rate was reduced by 16, 22, 26, and 30%, resp.). Physiological saline, as a control, atropine (50 μg), and hexamethonium (50 μg) did not affect the drop rate. Atropine (20 μg) partially abolished the contraction produced by 50 μg of ACh; hexamethonium (50 μg) did not have an effect. Cerulein (50 μg) produced a relaxation of the sphincter; epinephrine (50 μg) produced a contraction. Both sympathetic and parasympathetic mechanisms seem to play a role in the regulation of sphincteric activity of the main pancreatic duct in dogs.

5883 CONTROL OF LOWER-ESOPHAGEAL-SPHINCTER CONTRACTILE ACTIVITY BY MOTILIN IN CONSCIOUS DOGS. (Eng.) Itoh, Z.; Aizawa, I.; Honda, R.; Hiwatashi, K.; Couch, E. F. (Gunma Univ. Sch. Medicine, Maebashi, Japan 371). *Am. J. Dig. Dis.* 23(4):341-345; 1978.

To investigate whether the lower esophageal sphincter (LES) contractions in the interdigestive state may be controlled by motilin, the effect of synthetic motilin on contractile activity in the LES and in the stomach was studied in five healthy dogs by means of chronically implanted strain gauge force transducers. Motilin produced strong contractions in the LES and the stomach simultaneously after i.v. doses ranging from 0.3 to 2.7 μg/kg/hr, which were similar to the naturally occurring interdigestive contractions in the LES and the stomach. However, these contractions could be induced only in the interdigestive state; motilin infusion in the digestive state brought about no significant effect on either the LES or the stomach. Motilin-induced contractions in the LES and the stomach were instantly abolished by food ingestion. It is considered that the contractions induced by motilin are identical with the naturally occurring interdigestive contractions in the LES and that these contractions are the most orad component of the interdigestive cyclic recurring caudad-moving bands of strong contractions in the dogs.

5884 MORPHOLOGICAL ASPECTS OF BILIARY DYNAMICS [Abstract]. (Eng.) Kyosola, K.; Rechardt, L. (No affiliation given). *Acta Anat.* 99(3): 287; 1977.

5896 EFFECT OF ETHANOL ON CANINE GASTRIC EPITHELIAL ULTRASTRUCTURE AND TRANSMUCOSAL POTENTIAL DIFFERENCE. (Eng.) Eastwood, G. L.; Erdmann, K. R. (Univ. Massachusetts Medical Sch., 55 Lake Ave. North, Worcester, MA 01605). *Am. J. Dig. Dis.* 23(5):429-435; 1978.

Changes in the gastric transmucosal potential difference (PD), as an indicator of the integrity of the gastric mucosal barrier, were correlated with morphological evidence of injury in dogs that had received either intragastric saline or 5, 10, 15, or 30% ethanol. Progressively greater decreases in PD occurred after 10, 15, and 30% ethanol, resp. The drop in PD became significant 2 min after the installation of 10% ethanol and 1 min after 15 and 30% ethanol. Increasing degrees of morphological damage were accompanied by greater, more rapid changes in PD. Furthermore, ultrastructural changes occurred within surface epithelial cells, not in the deeper parietal or zymogen cells, and initially did not involve disruption of the apical cell membrane. Typically, the tight junctions also were not affected, although in a minority of dogs, small bleblike separations of the tight junctions were seen. The authors consider the gastric mucosal barrier to be represented morphologically by the interconnecting sheet of gastric epithelial cells and that ethanol breaks the barrier by first causing intracellular injury.

5897 GASTRIC SECRETORY RESPONSE TO INTRAVENOUS AMINO ACIDS IN EVISCERATED DOGS. (Eng.) Mariano, E. C.; Landor, J. H. (New Jersey Rutgers Medical Sch., Piscataway, NJ). *Arch. Surg.* 113(5): 611-614; 1978.

Eight dogs, four with intact vagi and four with vagotomy, were studied to see if the gastric secretory effect of i.v. administered L-amino acids is mediated by a gastrointestinal hormone or hormones. Amino acid infusion produced a significant secretory response in denervated stomachs (from 19.6 µEq/hr to 208 µEq/hr, $p<0.005$) and in innervated stomachs (from 157 µEq/hr to 943 µEq/hr, $p<0.025$). When the known sites of formation of gastrointestinal hormones were removed by resection of antrum, duodenum, pancreas, jejunum, ileum, and colon, the gastric stimulatory effect of amino acids was not changed significantly in denervated stomachs but was greatly increased in innervated stomachs ($p<0.025$). It is concluded that amino acids have a direct effect on parietal cell secretion that is not dependent on the intermediary release of a stimulatory hormone, and that evisceration enhances this effect in dogs with intact vagi.

5898 OXYGEN CONSUMPTION DURING CIMETIDINE AND PROSTAGLANDIN E_2 INHIBITION OF ACID SECRE-

TION. (Eng.) Cheung, L. Y.; Moody, F. G.; Larson, K.; Lowry, S. F. (Washington Univ. Sch. Medicine. 4960 Audubon Ave., St. Louis, MO 63110). *Am. J. Physiol.* 234(5):E445-E450; 1978.

Changes in oxygen consumption were determined during cimetidine and 16,16-dimethyl prostaglandin E_2 (PGE_2) inhibition of acid secretion in exteriorized segments of the greater curvature of dog stomach. Acid secretion was stimulated with an i.v. infusion of histamine (1.0 µg/kg/min) in five groups of dogs; the four experimental groups received cimetidine (50 µg/kg/min, i.v.), PGE_2 (0.4 µg/kg/min, i.v., or 25 µg/period, luminally), or thiocyanate (2.5 mg/kg/min, i.v.) during the histamine infusion. Steady-state acid secretion during histamine infusion correlated well with O_2 consumption ($r=0.85$, $p<0.01$). Cimetidine and PGE_2 inhibition of acid secretion produced a reduction of oxygen consumption to resting levels. In contrast, oxygen consumption did not decrease appreciably during thiocyanate inhibition of acid secretion. These observations suggest that the inhibitory action of cimetidine and PGE_2 precedes, whereas that of thiocyanate is at a point beyond, the transfer of energy to the process of acid production.

5899 THE EFFECT OF CIMETIDINE ON STRESS ULCERS.

(Eng.) Sufian, S.; Sugimachi, K.; Leahy, J.; Matsumoto, T. (Hahnemann Medical Coll. and Hosp., 230 N. Broad St., Philadelphia, PA 19102). *Int. Surg.* 63(3):143-146; 1978.

The effect of cimetidine on stress ulcers was studied in male Wistar rats with ulcers induced by cold and restraint. The animals were divided into six groups: group I (5 rats), no stress, no treatment; group II (50 rats), stressed but no treatment; group III (10 rats) pretreated with saline then stressed; group IV (10 rats) pretreated with antacid then stressed; group V (40 rats) pretreated with cimetidine (40 µg/kg), then stressed; and group VI (20 rats) stressed then treated with cimetidine. Ulcers less than 1 mm were not considered as countable results. Ulcers occurred in the glandular portion of the stomach and were frequently associated with hemorrhage and edema. In group II, 96% of the rats developed ulcers compared to none in group I. The severity of the ulcer for group II was calculated as 2.2 on a scale of 0 to 3 (0; 1-15; 16-30; or >30 ulcers, resp.). Pretreatment with saline or antacid (groups III and IV) had no protective value; all rats in both groups developed ulcers. The severity of the ulcers was slightly lower in the antacid treated (1.9) compared with the saline treated group (2.5). Thirty-four percent in group V and 65% in group VI developed ulcers. In group V, the incidence of ulcers was markedly reduced, and the severity of the ulcer (0.5) was markedly less. Post-treatment with cimetidine decreased the severity (1.2) more than in other groups but was not as effective as pretreatment. Cimetidine seems to be very effective in preventing stress-induced ulcers in rats when instilled in the stomach prior to the stress.

5900 A PHYSIOLOGICAL ROLE FOR LUMINAL GASTRIN?

(Eng.) Fiddian-Green, R. G.; Farrell, J.; Havlichek, D., Jr.; Kothary, P.; Pittenger, G. (Univ. Michigan Medical Center, Ann Arbor, MI 48109). *Surgery* 83(6):663-668; 1978.

The possibility that luminal gastrin might participate in the physiological control of acid secretion was examined in 45 healthy subjects. Exogenous gastrin was infused into the lumen of the stomach in concentrations (100, 200, and 400 pg/ml) that previously had been detected as immunoreactive gastrin (IRG) in gastric juice, and the secretory responses were monitored with the intragastric titration technique. Exogenous luminal gastrin induced a dose-related increase in the background secretory response to gastric distention with water ($p<0.001$). The secretory responses to exogenous gastrin were accompanied by the disappearance of the gastrin from gastric juice ($p<0.001$) and, in some circumstances, by the appearance of IRG in the circulation ($p<0.005$). Inhibition of the secretory response to distention with water, induced by substituting saline for water or by administering Boots' secretin, was accompanied by the appearance of endogenous IRG in gastric juice ($p<0.05$). Recovery in secretory rate, after these inhibitory stimuli, was accompanied by the disappearance of the endogenous IRG from gastric juice ($p<0.05$), just as the secretory response to exogenous gastrin had been accompanied by the disappearance of exogenous gastrin from gastric juice. The inhibitory stimuli did not alter the concentrations of IRG in serum. These data suggest that luminal gastrin may participate in the physiological control of acid secretion.

5901 INFLUENCE OF VAGUS ON MECHANISMS FOR STIMULATION AND INHIBITION OF GASTRIN RELEASE.

(Eng.) Schafmayer, A.; Teichmann, R. K.; Swierczek, J. S.; Rayford, P. L.; Thompson, J. C. (Univ. Gottingen, Gottingen, W. Germany). *Surgery* 83(6):711-716; 1978.

To clarify the means by which vagotomy influences gastrin release, the gastrin response to food, bombesin (1 µg/kg/hr), and somatostatin (2.5 and 5.0 µg/kg/hr) plus food was determined in dogs before and after truncal vagotomy. Vagotomy caused an increase in basal gastrin levels and in gastrin release after bombesin and food (from 49 ± 5 to 80 ± 5 pg/ml, $p<0.05$; from 51.4 to 193.4 ng/min/ml, $p<0.05$; and from 15.2 to 19.6 ng/min/ml, $p<0.05$, resp.). Vagotomy augmented somatostatin suppression of food-stimulated gastrin release in a dose-dependent manner. The authors suggest that vagotomy causes a loss of both stimulatory and inhibitory vagal effects on gastrin release. Loss of vagal inhibition results in increased gastrin release to bombesin and food. Loss of vagal stimulation results in intensification of somatostatin-induced inhibition of postprandial gastrin release.

5902 CHARACTERISTICS AND TACHYPHYLAXIS OF GASTRIN-STIMULATED GASTRIC ACID SECRETION IN

THE CAT. (Eng.) Hirst, B. H.; Labib, L. A.; Reed, J. D. (Medical Sch., Univ. Newcastle upon Tyne, Newcastle upon Tyne NE1 7RU, England). *J. Physiol. (Lond.)* 276:1-11; 1978.

To determine the effects of tachyphylaxis of acid secretion on the shape of the dose-response curve to pentagastrin and on maximum acid secretion in response to pentagastrin, conscious cats were fitted with chronic cannulated gastric fistulae and subjected to single- and multiple-dose assay systems. There was a significant positive correlation (r=0.557) between the peak acid secretion in response to pentagastrin (8 μg/kg/hr) and body weight; male cats, which were heavier, secreted significantly greater amounts of acid in response to pentagastrin than females. The difference was lessened, but not eliminated, by expressing the acid output in terms of body weight. Pentagastrin stimulated a dose-dependent increase in acid secretion in the range 0.5-32 μg/kg/hr when the response to each dose was assayed on separate occasions. Pentagastrin (64 μg/kg/hr) did not produce a further increase in acid secretion. The acid response to pentagastrin (1-16 μg/kg/hr) assayed on a single occasion by a continuous infusion method showed a dose-response relationship up to 8 μg/kg/hr where it reached a plateau of secretion. There was no difference between the two methods of assaying the gastric acid-stimulating activity using doses of pentagastrin up to 8 μg/kg/hr. The acid secretion in response to pentagastrin (8 μg/kg/hr) reached a maximum after 45 min of stimulation and thereafter showed tachyphylaxis. Over a 5-hr period, there were at least two phases of tachyphylaxis distinguishable. During the period of 0.75-2.5 hr of stimulation, there was a fast phase of tachyphylaxis (-32.0 μEq H^+/kg/15 min). This was followed by a slow phase of tachyphylaxis (-9.4 μEq H^+/kg/15 min), 2.75-5 hr of stimulation. The absolute rate of the fast phase of tachyphylaxis of acid secretion (μEq H^+/kg/15 min) increased with increasing doses of pentagastrin, but the rates of tachyphylaxis were similar when expressed as a percentage of the peak acid response to the particular dose of pentagastrin (5.1-7.8%/15 min). Synthetic human gastrin-17, the synthetic C-terminal decapeptide of human gastrin, and the C-terminal tetrapeptide of gastrin elicited comparable rates of tachyphylaxis. Two possible receptor models for the tachyphylaxis of gastrin-stimulated acid secretion, seen in other biological systems, are discussed: an allosteric model proposing the existence of a second receptor site with progressive occupation, leading to desensitization of the stimulatory receptor site and a model that proposes an agonist-induced conformational change in the receptor that is incompatible with further activation.

5903 EFFECT OF GLUCOCORTICOIDS ON GASTRIN SECRETION IN MAN. (Eng.) Seino, S.; Seino, Y.; Matsukura, S.; Kurahachi, H.; Ikeda, M.; Yawata, M.; *et al.* (Kobe Univ. Sch. Medicine, Kusunoki-cho, Ikuta-ku, Kobe, Japan). *Gut* 19(1):10-13; 1978.

To investigate the acute and chronic effects of glucocorticoids on plasma gastrin levels, plasma gastrin levels were measured by radioimmunoassay in 6 patients with Cushing's syndrome, 10 patients on long-term treatment with glucocorticoids (total dose >500 mg for >3 weeks), 11 normal subjects on short-term glucocorticoid treatment (30 mg/day, 3 days, p.o.), and 45 normal controls. The fasting plasma gastrin levels in the patients with Cushing's syndrome and in those on long-term steroid treatment (105 ± 20 pM and 73 ± 10 pM, resp.) were significantly higher than those in the untreated normal subjects and those on short-term therapy (43 ± 2 pM and 43 ± 3 pM, resp., $p<0.01$). The plasma gastrin response to food was tested in six normal untreated subjects, six patients on short-term treatment, and six patients on long-term treatment. The mean basal and 30-min postprandial plasma gastrin levels in the patients on long-term therapy (74 ± 10 pM and 231 ± 41 pM, resp.) were significantly higher than the corresponding values in untreated normal subjects and those on short-term steroid treatment ($p<0.05$). The i.v. infusion of 250 or 500 mg of hydrocortisone had no significant influence on gastrin secretion in five normal subjects. The results suggest that chronic exogenous or endogenous excess of glucocorticoids leads to hypergastrinemia, whereas an acute excess has no significant influence on gastrin secretion.

5904 DISTRIBUTION OF PROSTAGLANDIN-SENSITIVE ADENYLATE CYCLASE IN HUMAN UPPER GASTROINTESTINAL TRACT. (Eng.) Simon, B.; Kather, H. (Medizinische Universitatsklinik, Bergheimerstrasse 58, D-6900 Heidelberg, W. Germany). *Digestion* 17 (3):264-267; 1978.

The topographical distribution of the prostaglandin-sensitive adenylate cyclase in the upper gastrointestinal tract was studied in human biopsy specimens. The prostaglandin-sensitive enzyme was almost evenly distributed throughout the fundic, antral, and duodenal mucosa. The enhancement of enzyme activity in the presence of a maximally effective prostaglandin concentration (0.3 mM) exceeded basal levels by about 200%. The H_2-receptor blocking agent cimetidine (up to 50 mM) and the β-blocking agent propranolol (up to 50 mM) did not reduce the prostaglandin-sensitive enzyme system in contrast to their inhibitory effects on their respective agonists. The physiological role of the prostaglandin-sensitive adenylate cyclase in gastric and duodenal function, however, remains to be established.

5905 METHYLATED ANALOGUES OF PROSTAGLANDIN E_2 AND THE GASTRIC MUCOSAL BARRIER. (Eng.) Kenyon, G. S.; Ansell, I. F.; Carter, D. C. (Edinburgh Univ. Medical Sch., Edinburgh, Scotland). *Prostaglandins* 15(5):779-794; 1978.

The effects of 15(R)-methyl prostaglandin E_2 methyl ester (15 MPG) and 16,16-dimethyl prostaglandin E_2 methyl ester (16DMPG) on gastric mucosal permeability to Na^+ and H^+ were investigated in three male mongrel dogs prepared by antrectomy and construction of a vagally-denervated fundic pouch. It was also deter-

ed if the adverse effects that occur following
es of 16DMPG are of a magnitude liable to be
d clinically to suppress gastric secretion.
PG did not increase mucosal permeability to either
when given topically (18.75-300 μg) or i.v. (30
and did not affect permeability increases induced
topical 5 mM sodium taurocholate in acid solution.
MPG caused significant ($p<0.05$) increases in net
gain when given topically (18.75-75 μg) but did
affect net H^+ loss from the pouch lumen. Attempts
use higher doses of 16DMPG were abandoned because
bleeding from the pouch, and perforation in one
mal. It is conceivable that 16DMPG could cause
erse effects on the gastric mucosal barrier if
d to suppress gastric secretion therapeutically.
PG does not share this potentially harmful
perty and remains worthy of further study as
inhibitor of gastric secretion having thera-
tic promise.

06 EFFECTS OF INTRA-ARTERIAL INFUSION OF PROSTAGLANDIN E_1 ON GASTRIC SECRETION
BLOOD FLOW. (Eng.) Cheung, L. Y.; Lowry, S.
(Washington Univ. Sch. Medicine, 4960 Audubon
., St. Louis, MO 63110). *Surgery* 83(6):699-704;
8.

ce prostaglandin E_1 (PGE_1) is not only an effec-
e inhibitor of acid secretion but also a potent
odilator, it provides an opportunity to study
ssociative changes in gastric acid secretion and
od flow. The effect of intra-arterial infusion
PGE_1 on gastric total and mucosal blood flow
acid secretion was studied in an exteriorized,
mbered preparation of canine fundic stomach.
al gastric blood flow was measured simultaneously
venous outflow and by gamma-labeled microspheres.
cosal blood flow also was measured by microspheres.
intra-arterial infusion of PGE_1 at 1.0 μg/min
pletely inhibited histamine-stimulated acid se-
etion. This inhibition was accompanied by a sig-
ficant increase in both total ($p<0.01$) and mucosal
od flow ($p<0.01$). The ratio of mucosal to total
od flow remained unchanged during histamine (1.0
kg) stimulation (78 ± 4%) and PGE_1 (1.0 μg/min)
ibition (79 ± 4%). The results suggest that in-
ition of acid secretion can occur in the face of
reased blood flow. This observation is contrary
the generally accepted concept that inhibition
acid secretion always is associated with a de-
ease in mucosal blood flow.

07 STIMULATION OF MUCUS AND NONPARIETAL CELL SECRETION BY THE E_2 PROSTAGLANDINS. (Eng.)
lton, J. P.; Palmer, D.; Cohen, M. M. (Univ. Bri-
sh Columbia, 700 W. 10 Ave., Vancouver, British
lumbia V5Z 1L5, Canada). *Am. J. Dig. Dis.* 23(4):
9-364; 1978.

investigate the mechanism of the protective ac-
on of prostaglandin E_2 (PGE_2) on the rat gastric
cosa, the effects of PGE_2, 15-methyl prostaglandin
(15M), and 16,16-dimethyl prostaglandin E_2 (16DM)
gastric mucus and nonparietal cell secretion
re measured. Alcian blue binding was used as
a measure of gastric mucus. Applied topically, all three agents stimulated nonparietal cell secretion, and PGE_2 and 16DM stimulated the secretion of mucus ($p<0.01$), increasing the fraction in the gastric contents but not that adherent to the mucosa. Topical 15M did not stimulate the production of mucus. Given i.v., all three agents increased the amount of mucus in the gastric contents ($p<0.01$) without altering the amount of mucus bound to the mucosa. The prostaglandins had no effect on nonparietal cell secretion when given i.v. Topical application of each agent produced a highly significant ($p<0.01$) reduction in acid output. These effects could be relevant to the ability of the E_2 prostaglandins to protect the gastric mucosa from damage.

5908 EFFECTS OF E PROSTAGLANDINS ON CANINE GASTRIC POTENTIAL DIFFERENCE. (Eng.)

Dajani, E. Z.; Callison, D. A.; Bertermann, R. E. (Dept. Biological Res., Searle Lab., Box 5110, Chicago, IL 60680). *Am. J. Dig. Dis.* 23(5):436-442; 1978.

Measurement of the gastric transmucosal potential difference (PD) was used to study the effect of gastric antisecretory prostaglandins on the integrity of the gastric mucosa of the Heidenhain pouch dog. The intragastric administration of SC-29333 [(±)-15-deoxy-16-α,β-hydroxy-16-methyl PGE_1 methyl ester] at 10 and 30 μg/kg slightly but significantly increased the transmucosal PD when compared to vehicle control ($p<0.05$). In addition, SC-29333 administered either i.v. or intragastrically significantly inhibited the PD fall induced by aspirin ($p<0.05$). In contrast, the intragastric administration of 16,16-dimethyl PGE_2 methyl ester (Me-PGE_2) significantly lowered the transmucosal PD ($p<0.05$) and failed to modify the actions of aspirin on the integrity of the gastric mucosa. However, the i.v. administration of either prostaglandin did not affect the basal transmucosal PD values. These studies suggest that SC-29333 may strengthen the integrity of the gastric mucosal barrier against aspirin, and this effect could have important therapeutic potential.

5909 EFFECTS OF SYNTHETIC VASOACTIVE INTESTINAL PEPTIDE (VIP), SECRETIN AND THEIR PARTIAL SEQUENCES ON GASTRIC SECRETION. (Eng.)

Makhlouf, G. M.; Zfass, A. M.; Said, S. I.; Schebalin, M. (Medical Coll. Virginia, Richmond, VA 23298). *Proc. Soc. Exp. Biol. Med.* 157(4):565-568; 1978.

The effects of synthetic porcine vasoactive intestinal peptide (VIP) and secretin on pentagastrin-stimulated gastric secretion were compared in dogs with gastric fistulae. The infusion of both synthetic VIP (0.5 μg/kg/min, for 7.5 min) and synthetic secretin (0.05 μg/kg/min) produced a prompt inhibition of acid secretion, which reached a nadir in the first 30 min. VIP inhibited the maximal pepsin response by 65 ± 10% ($p<0.01$). The inhibition of pentagastrin-stimulated acid secretion by VIP was significantly greater at the lowest dose of pentagastrin (0.25 μg/kg/hr) than at the highest dose (16 μg/kg/hr, 57 ± 7% versus 23 ± 7%, $p<0.01$). Dose-response analysis (response versus response/dose) indicated that inhibition was of the competitive type. An apparent inhibitor dissociation constant for VIP was calculated to be 0.43 μg/kg/min. Percent inhibition of acid secretion by secretin did not vary with the dose of pentagastrin and was consistent with inhibition of the noncompetitive type. Carboxyl-terminal partial sequences of VIP and secretin, at approximately 10 times the molar doses of the parent peptides, had no detectable inhibitory effect. Synthetic VIP appears to be less effective than synthetic secretin, at least in terms of the doses required for an equivalent degree of inhibition of gastric secretion.

5910 COMPARISON OF GASTRIC RESPONSES TO SMALL INTESTINAL RESECTION AND BYPASS IN RATS. (Eng.) Bowen, J. C.; Paddack, G. L.; Bush, J. C.; Wilson, R. J.; Johnson, L. R. (Ochsner Clinic, 1514 Jefferson Highway, New Orleans, LA 70121). *Surgery* 83(4):402-405; 1978.

To clarify the divergent gastrin responses to small intestinal resection and bypass, male Sprague-Dawley rats were subjected to either 90% intestinal resection (n=10), 90% intestinal bypass (n=10), or a sham intestinal operation (n=10). After 8 weeks, fasting serum gastrin levels were increased significantly ($p<0.001$) in the resection group (36.6 ± 2.6 fmol/ml), as compared with the sham group (20.4 ± 2.4 fmol/ml) and the bypass group (23.3 ± 4.0 fmol/ml). Antral gastrin levels also were increased significantly ($p<0.01$) in the resection group (2.92 ± 0.09 nmol/g wet weight) but were not significantly different in the bypass group (2.55 ± 0.17 nmol/g) as compared with the sham group (2.43 ± 0.12 nmol/g). Oxyntic gland carbonic anhydrase followed the same pattern, i.e., increased significantly ($p<0.02$) in the resection group (44.3 ± 3.3 U/mg protein) but not significantly different in the bypass group (38.5 ± 2.4 U/mg protein) as compared with the sham group (33.8 ± 2.2 U/mg protein). Fundic pepsinogen activity was not significantly changed in either the resection or bypass groups; it was the only measured parameter that did not increase after small intestinal resection. The data show that, in contrast with jejunoileal bypass, massive small intestinal resection in the rat causes a significant increase in serum gastrin with concomitant trophic changes in the stomach. It is concluded that the small intestine is an important regulator of gastric function, even when removed from intestinal continuity and left *in situ* by intestinal bypass.

5911 PLASMA GASTRIN LEVELS FOLLOWING DIETARY PROTEIN STIMULATION. (Spa.) Varas Lorenzo, M. J.; Luque Gonzalez, M. T. (Hospitalet de Llobregat, Barcelona, Spain). *Rev. Esp. Enferm. Apar. Dig.* 51(4):363-380; 1977.

SECRETION AND METABOLISM

Pancreas

5932 EVIDENCE FOR PYLOROPANCREATIC REFLEX FOR PANCREATIC EXOCRINE SECRETION. (Eng.)
ebas, H. T.; Yamagishi, T. (Dept. Surgery, Univ.
British Columbia, Vancouver, Canada). *Am. J. Phys-*
iol. 234(5):E468-E471; 1978.

In seven dogs provided with an innervated pouch of the pyloric antrum, a gastric fistula, and a chronic pancreatic fistula, the effect of graded antral distention on pancreatic exocrine secretion was studied to gain information on the role of a gastropancreatic reflex in pancreatic secretion. The effect of antral distention was tested both when gastrin release was promoted (alkaline distention) and when gastrin release was blocked (acid distention). These studies were performed both before and after transthoracic truncal vagotomy. Graded alkaline antral distention caused graded rise in protein-rich pancreatic secretion ($p<0.05$ at 10 min; $p<0.001$ at 20, 30, and 40 min) and a graded increase in the concentration of serum immunoreactive gastrin. A similar pancreatic protein secretory response was also seen with graded acid distention, although this time no rise in serum gastrin concentration occurred. Pancreatic response to antral distention with either alkali or acid was completely inhibited by pretreatment of the animals with systemic atropine (0.2 mg/kg, s.c.). Truncal vagotomy reduced pancreatic response to alkaline antral distention by 90% but completely abolished pancreatic response to distention of the antrum with acid. These studies provide evidence for a pyloropancreatic reflex mechanism for pancreatic secretion that is cholinergic and requires intact long vagal pathways.

5933 EFFECT OF CONTINUOUS JEJUNAL PERFUSION OF ELEMENTAL AND COMPLEX NUTRITIONAL SOLUTIONS ON PANCREATIC ENZYME SECRETION IN HUMAN SUBJECTS. (Eng.) Vidon, N.; Hecketsweiler, P.; Butel, J.; Bernier, J. J. (INSERM U. 54, Hopital Saint-Lazare, Paris, France). *Gut* 19(3):194-198; 1978.

To determine the effect of jejunal perfusion of an elemental diet on pancreatic enzyme secretion, pancreatic lipase and chymotrypsin secretion in response to elemental diets and a crushed food homogenate was studied in 17 normal subjects. The solutions were infused at constant flow rates (2 ml/min for crushed food; 1, 2, and 3 ml/min for elemental diet) at the ligament of Treitz with polyethylene glycol as a nonabsorbable marker. A triple lumen tube was used, enabling collection of secretions at 35 and 70 cm from the infusion point. Pancreatic secretion of lipase and chymotrypsin was found to vary with the elemental diet flow rate. However, for the same caloric value, enzyme flow rate was greater with the crushed food homogenate than with the elemental diet. This rate was directly related to the nitrogenous load; the load was 13.89 ± 0.30 mg/min with the crushed food homogenate at 2 ml/min, whereas the values for the elemental diet at 1, 2, and 3 ml/min were 3.39 ± 0.05, 6.60 ± 0.12, and 10.17 ± 0.16 ml/min, resp. There was no significant difference between enzyme secretion with either diluted or undiluted elemental diet when the caloric value was kept constant. The results indicate that pancreatic enzyme secretion occurs in response to jejunal perfusion of both elemental diet and crushed food homogenate. Pancreatic enzyme secretion increases with the caloric and nitrogenous loads infused, but the volume or osmolality of the infused solution does not affect it. The findings imply that the only means of significantly reducing pancreatic secretion during the treatment of pancreatitis may be through parenteral feeding.

5934 EFFECTS OF A PROTEIN MEAL, INTRADUODENAL HCl, AND OLEIC ACID ON PORTAL AND PERIPHERAL VENOUS SECRETIN AND ON PANCREATIC BICARBONATE SECRETION. (Eng.) Boden, G.; Wilson, R. M.; Essa-Koumar, N.; Owen, O. E. (Temple Univ. Health Sciences Center, Philadelphia, PA 19140). *Gut* 19(4):277-283; 1978.

To determine the role of secretin in postprandial pancreatic water and bicarbonate secretion, the effect of a protein meal on immunoreactive secretin (IRS) concentration was studied in dogs and humans using a radioimmunoassay of improved sensitivity (8 pg/ml). After a 600-g protein meal, pancreatic bicarbonate secretion (PBS) in the dogs increased markedly during the first 15 min after feeding ($p<0.01$), and proximal duodenal pH decreased from 6.2 to 4.3 ($p<0.001$). Portal and peripheral IRS concentrations, however, remained unchanged in eight dogs and five patients with liver cirrhosis after ingesting a meal (meat in the dogs, mixed in the humans). An alkaline solution of sodium oleate (pH 9.2) stimulated PBS but not IRS when infused in dogs. Intraduodenal administration of various amounts of HCl in dogs demonstrated that acid-stimulated PBS was invariably accompanied by rises in peripheral venous IRS concentration. It is concluded that the postprandial stimulation of PBS involves mechanisms more complex than acid-stimulated secretin release.

5935 QUANTITATION OF ULTRASTRUCTURAL CHANGES IN MOUSE PANCREATIC ACINAR CELLS CAUSED BY FOREIGN SERUM. (Eng.) Nevalainen, T. J. (Lab. Electron Microscopy, Univ. Turku, Kiinamyllynkatu 10, SF-20520 Turku 52, Finland). *Exp. Cell Biol.* 46(4):193-198; 1978.

Quantitative changes in the pancreatic acinar cell organelles were observed in BALB/c mice injected i.p. with 1.0 ml fresh rabbit serum to study the mechanism by which serum initiates pancreatitis. Groups of five mice each were killed at 0, 1, 3, 6, and 12 hr after the serum injection. Pancreatic tissue was processed for electron microscopy by glutaraldehyde and osmium tetroxide fixation and Epon embedding. The proportions of acinar cell cytoplasm (volume fractions) occupied by zymogen granules, granular endoplasmic reticulum, Golgi apparatus, mitochondria, and lysosomes (including autophagosomes) were determined by the point counting method from electron micrographs. The volume fraction of lysosomes increased during the first 3 hr and remained markedly elevated up to 12 hr. The volume fractions of mitochondria and endoplasmic reticulum decreased slightly in 12 hr. The volume fraction of zymogen granules increased from 12% to 28% in 12 hr. It is concluded that the secretory mechanism of pancreatic acinar cells is injured by the foreign serum, and that this injury causes accumulation of zymogen granules and increas autophagic activity in the acinar cells.

5936 SECRETORY PATTERN AND PATHOLOGICAL STUDY OF THE PANCREAS OF STEROID-TREATED RATS. (Eng.) Bourry, J.; Sarles, H. (Unite de Recherches de Pathologie Digestive, U31, INSERM 46, chemin de la Gaye, 13009 Marseille, France). *Am. J. Dig. Dis* 23(5):423-428; 1978.

To gain information on the mechanism of steroid-induced pancreatitis, modifications of pancreatic secretion induced by prolonged administration of corticosteroids were studied in rats, and these physiological modifications were correlated with

ıe development of pancreatic lesions. Male Sprague-
wley rats received prednisolone (2.5 mg/kg/day)
drinking water during 1.5 to 12.5 months, and an
ual group of matched controls received water alone.
e most significant ($p<0.1$ due to the small sample
ze) pathological effects at 1.5-12.5 months of
eroids were dilatation of acini, flattening of
ct epithelium, and the presence of protein plugs
the ducts. The most significant ($p<0.05$) func-
onal modifications at 9-11 months of treatment
re increased concentration and output of proteins
th in basal and stimulated pancreatic secretion of
eroid-treated rats. This is very similar to the
sults observed previously in alcohol-induced pan-
eatitis. It is assumed that the hyperconcentra-
on could be at least partly responsible for pre-
pitation of proteins and the precipitate formation
r the lesions. For the large group of acute or
ronic pancreatic lesions characterized by the
rmation of protein plugs in the ducts, the term
tarrhal pancreatitis is proposed.

37 THE PERMEABILITY OF THE SECRETIN STIMULATED EXOCRINE PANCREAS TO NON-ELECTRO-
TES.

(Eng.) Dewhurst, D. G.; Hadi, N. A.; Hut-
n, D.; Scratcherd, T. (Dept. Physiology, Univ.
effield, Sheffield S10 2TN, England). *J. Physiol.
ond.)* 277:103-114; 1978.

method of measuring the permeability of the pan-
eas by determining the apparent reflection co-
ficient (σ^A) is described in the isolated cat
ncreas secreting maximally under the influence of
cretin. The principle is to add a nonelectrolyte
the perfusate that will create an osmotic gra-
ent ($RT\sigma\Delta C$) counter to that of active transport
d reduce the secretion rate. This effect is com-
red with that of an equal concentration (0.1 M)
sucrose ($RT\Delta C$, $\sigma=1$). The apparent reflection
efficient is obtained by dividing the percentage
duction in the secretion rate due to the test
lecule with that due to sucrose. For every 10-mM
crease in sucrose concentration in the perfusate,
e secretion rate was inhibited by 7.1%. It was
timated that an osmotic gradient of 131 mOsm/
water will cause zero flow rate. This gradient
a measure of the pressure required to counter-
t the local osmotic gradient set up by active
ansport and is equivalent to about 3.4 atmos-
eres. Nonelectrolytes with molecular volumes
eater than about 85 cm^3/mol were relatively
permeable; below this value, they entered the
ncreatic juice with increasing ease as the
lecular volume decreased. σ^A for urea was 0.17;
hanediol, 0.27; thiourea, 0.51; glycerol, 0.69;
eatinine, 0.81; erythritol, 0.91; arabinose, 0.96;
lose, 0.98; and sorbitol, 0.98. For molecules
th σ^A between 0.81 and 1.0, an osmotic load of
1 M increased both the concentration of sodium
us potassium and the concentration of chloride
us bicarbonate by about 50 mM. Whereas the
tion change was almost exclusively one of sodium,
at of the anions was preferentially an increase
chloride. For compounds with σ^A between 0 and
81, the concentration of sodium plus potassium
s proportional to σ^A. It is concluded that the
ncreas is more permeable than is the gallbladder
of rabbit, fish, and bullfrog, the proximal tubule of the kidney of rat and the small intestine of bullfrog, but is probably similar to that of the small intestine of guinea pig and man.

5938 THE EFFECT OF CALCITONIN ON SECRETIN-STIMULATED PANCREATIC SECRETION IN MAN.

(Eng.) Odes, H. S.; Barbezat, G. O.; Clain, J. E.; Bank, S. (Groote Schuur Hosp., Observatory, CP, 7925, South Africa). *S. Afr. Med. J.* 53(6):201-203; 1978.

The effect of a small dose of calcitonin on pancreatic secretion was studied in six healthy subjects to gain information concerning the use of calcitonin in the treatment of pancreatitis. After steady-state secretion was achieved with a constant i.v. infusion of secretin (2 μg/kg/hr), either calcitonin (0.16, and 0.32 μg/kg/hr) or 0.15 M NaCl was infused over 80 min. Calcitonin did not affect pancreatic volume output or bicarbonate concentration, but amylase concentration and output were significantly inhibited ($p<0.025$) in comparison with those in eight controls who received saline. The color index in the duodenal juice was unchanged by calcitonin. No changes were observed in blood glucose or serum calcium concentrations. The failure of calcitonin to suppress hyperamylasemia in patients undergoing endoscopic retrograde cholangiography suggests that its use in pancreatitis may be limited.

5939 INHIBITION OF PANCREATIC SECRETION BY ENKEPHALIN AND MORPHINE IN DOGS.

(Eng.) Konturek, S. J.; Tasler, J.; Cieszkowski, M.; Jawarek, J.; Coy, D. H.; Schally, A. V. (Inst. Physiology, 31-531 Krakow, ul. Grzegorzecka 16, Poland). *Gastroenterology* 74(5, Part 1):851-855; 1978.

The nature and extent of enkephalin- and morphine-induced inhibition of pancreatic bicarbonate and protein secretion were studied in dogs with chronic pancreatic fistulae after administering exogenous secretin (2.0 U/kg/hr or graded doses of 0.5-8.0 U/kg/hr) or an octapeptide of cholecystokinin (0.5 μg/kg/hr) and stimulants for the endogenous release of these hormones. Both enkephalin and morphine (each at 40 μg/kg/hr) competitively inhibited the pancreatic bicarbonate secretion induced either by exogenous secretin or duodenal acidification (by 36% with secretin; by 90% and 83% by enkephalin and morphine, resp., with acidification). This inhibition was partially reversed by naloxone (20 μg/kg/hr), an opiate antagonist. Opiate substances also profoundly inhibited pancreatic protein response to the octapeptide of cholecystokinin and to various stimulants of endogenous cholecystokinin release. It is concluded that enkephalin and morphine strongly inhibit the pancreatic responses to exogenous and endogenous stimulants by a mechanism involving separate opiate receptors.

5940 EFFECT OF CHRONIC PENTAGASTRIN, CHOLECYSTOKININ, AND SECRETIN ON PANCREAS OF RATS.

(Eng.) Petersen, H.; Solomon, T.; Grossman, M. I.

(Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Am. J. Physiol.* 234(3):E286-E293; 1978.

The effects of long-term treatment with pentagastrin, cholecystokinin (CCK), or secretin on pancreatic secretion in response to secretin and CCK, on the volume of endocrine and exocrine tissue in the pancreas, and on the ratio of chief cells to parietal cells in the stomach were studied in rats. Pentagastrin (1.5 mg/kg), 20% pure natural CCK (37.5 Ivy dog U/kg) or secretin (25 µg/kg) was given in a depot carrier s.c. 3 times daily for 15 days. The dose of CCK and secretin was submaximal for pancreatic secretion, whereas the dose of pentagastrin was supramaximal for gastric acid secretion. The pancreatic wet weight increased by 12% ($p<0.01$) in the rats treated with pentagastrin, 57% ($p<0.001$) in those treated with CCK, and 9% ($p<0.01$) in those treated with secretin. In CCK-treated rats, the maximal protein and bicarbonate outputs in response to CCK increased proportionately to the increase in pancreatic weight, but maximal bicarbonate and protein outputs in response to secretin were unaltered. The secretin-treated rats showed a lowered basal secretion of bicarbonate and a lowered sensitivity to secretin stimulation, but the maximal bicarbonate and protein outputs to secretin and CCK were unchanged. Pentagastrin treatment produced no significant changes in pancreatic responses to secretin or CCK. No significant difference was found between any groups for the calculated total mass of islets per pancreas. None of the treatment groups varied from the controls with respect to the ratio of chief cells to parietal cells. It is concluded that (1) the increase in pancreatic weight produced by repeated injections of cholecystokinin was accompanied by a proportional increase in functional capacity as reflected by the increased maximal bicarbonate and protein outputs in response to cholecystokinin, and (2) repeated administration of secretin decreased the sensitivity of the pancreas to secretin without altering maximal bicarbonate response.

5941 EFFECT OF SOMATOSTATIN ON EXOCRINE PANCREATIC SECRETION STIMULATED BY PANCREOZYMIN-SECRETIN OR BY A TEST MEAL IN THE DOG. (Eng.) Kayasseh, L.; Gyr, K.; Stalder, G. A.; Rittmann, W. W.; Girard, J. (Kantonsspital, CH-4004 Basel, Switzerland). *Hormone Res.* 9(3):176-184; 1978.

To determine whether somatostatin inhibits stimulated exocrine pancreatic function in dogs, exocrine pancreatic function was assessed in four animals with chronic duodenal and gastric fistulae by cannulating the pancreatic duct and collecting the duodenal contents. Pancreatic secretion was stimulated by the infusion of 2 Crick-Harper-Raper U of pancreozymin and secretin or by the administration of a liquid test meal, injected into the stomach through the gastric fistula. During both experiments, 3.5 µg/kg somatostatin was given as bolus injection followed by an infusion of 3.5 µg/kg/hr. Somatostatin caused a significant reduction in protein and amylase output and in the bicarbonate concentration during stimulation with pancreozymin-secretin ($p<0.02$, $p<0.05$, and $p<0.05$, resp.). Volume and bicarbonate were slightly decreased but not to a significant extent. Duodenal volume and the duodenal activities of trypsin and amylase were significantly reduced during test meal stimulation and somatostatin infusion ($p<0.05$, $p<0.01$, and $p<0.01$, resp.). Somatostatin is a potent inhibitor of exocrine pancreatic function, mainly influencing enzyme secretion.

Hepatobiliary Tract

5948 PHARMACOCHOLANGIOGRAPHY. (Eng.) Burgener, F. A. (Univ. Rochester Sch. Medicine and Dentistry, Rochester, NY). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 128(2):135-137; 1978.

To improve i.v. cholangiography, the effect of ouabain and atropine on bile flow and bile iodine concentration in i.v. cholangiography was investigated in four cholecystectomized dogs with complete bile diversion under general anesthesia and compared with the effect of sodium taurocholate. Iodipamide was administered i.v. with an initial priming dose of 50 mg/kg followed by a constant infusion of 2 mg/min/kg. Ouabain in stepwise increasing infusion rates (0.0625-0.25 μg/min/kg) had no significant effect. Atropine infusion (1 to 8 μg/min/kg) increased the bile iodine concentration up to 19%, but a 14% increase with a 5% reduction in bile flow was found with the lowest atropine dose. The lowest taurocholate infusion rate (0.16 mg/min/kg) resulted in the highest bile iodine concentration and lowest bile flow. Each increment in the taurocholate infusion rate (0.32-5.12 mg/min/kg) resulted in a significant increase in bile flow when compared with the preceding value ($p<0.05$). It is suggested that atropine premedication and low bile salt plasma levels might improve the opacification of the biliary tree, particularly in hepatic dysfunction by selectively reducing specific fractions of the basal bile flow.

5949 UPTAKE OF MACROMOLECULES BY RAT KUPFFER CELLS IN VITRO. (Eng.) Munthe-Kaas, A. C. (Norwegian Radium Hosp., Montebello, Oslo 3, Norway). *Exp. Cell Res.* 107(1):55-62; 1977.

Studies were carried out to determine whether pinocytosis plays a significant role in the normal physiology of the liver macrophage. Pinocytosis was studied in cultured rat Kupffer cells by using colloidal ^{198}Au, ^{131}I-labeled serum albumin, and ^{3}H-labeled sucrose as test substances. The kinetics of uptake as well as electron microscopy indicated that colloidal gold was pinocytosed directly as part of the fluid medium without prior absorption to the cell membrane. This process was resistant to cytochalasin B (CB), colchicine, and metabolic inhibitors at concentrations where phagocytosis would have been totally inhibited, but was reduced to less than 10% by low temperature. These data suggest that colloidal gold was taken up by micropinocytosis. Serum showed an inhibitory effect on colloidal gold and albumin uptake, whereas it stimulated sucrose uptake. Sucrose uptake was also more sensitive to CB. Distinct processes of macropinocytosis and micropinocytosis, with separate control mechanisms, may be occurring simultaneously in these cells.

5950 ULTRASTRUCTURE OF ADULT RAT HEPATOCYTES CULTURED ON FLOATING COLLAGEN MEMBRANES. (Eng.) Sattler, C. A.; Michalopoulos, G.; Sattler, G. L.; Pitot, H. C. (Duke Univ. Sch. Medicine, Durham, NC). *Cancer Res.* 38(6):1539-1549; 1978.

The ultrastructure of primary hepatocytes cultured for 2 to 17 days on floating collagen membranes was evaluated to test the value of this new technique for long-term culturing. A pellet of the hepatic cell suspension used to inoculate the collagen membranes contained some single cells and many aggregates of two, three, or four cells. Desmosomes were split during the perfusion, but tight junctions and gap junctions remained intact. By 2 days in culture, the hepatocytes had formed a monolayer of cells of polygonal shape with newly synthesized desmosomes between cells. Since the flexible floating collagen membrane decreases in size as the monolayer forms, the hepatocytes do not flatten out, as is characteristic of cells cultured on a rigid substrate. Hepatocytes in culture for 10 days or less exhibited large lamellar arrays of rough endoplasmic reticulum, well developed Golgi complexes, and structures resembling bile canaliculi, which possess tight junctions and desmosomes separating them from the intercellular space. Microfilaments oriented parallel to the plasma membranes of adjoining cells and in an intermeshed network at the edge of the monolayer and beneath the plasma membrane bordering the medium increased in size and number in older cultures. After 17 days in culture, the cells maintained tight junctions, desmosomes, Golgi complexes, and rough endoplasmic reticulum in small lamellar stacks and in small vesicles. Since hepatocytes on the floating collagen membrane retain most of the subcellular structural elements characteristic of normally functioning hepatocytes for 2.5 weeks, this system may be valuable for future experiments involving drug metabolism and carcinogenesis *in vitro*.

5951 LIVER ORIGIN OF HEPATOTROPHIC FACTOR(S). (Eng.) Demetriou, A. A.; Levenson, S. M. (Vanderbilt Univ. Sch. Medicine, Nashville, TN). *Surg. Forum* 28:383-384; 1977.

The hypothesis that the liver remnant following 70% hepatectomy is the site of production of a hepatotrophic factor(s) was tested. The effect of "conditioned tissue culture media" on the growth of hepatocytes *in vitro* was tested. Conditioned media refers to media in which cells have been grown in culture and then removed; the media is then used to cultivate other cells and the growth rate is assessed. At various time intervals following either hepatectomy or sham operation in male Sprague-Dawley rats, the media from normal hepatocytes were substituted with conditioned media from other hepatocyte monolayer cultures derived from normal, sham-hepatectomized, and 70% hepatectomized rats. Eight hours following media substitution, tritiated thymidine was added for 60 min. Twelve-hour conditioned media from regenerating liver cells produced a significant ($p<0.001$) stimulation of tritiated thymidine incorporation into the DNA of normal hepatocytes in culture, whereas media conditioned with normal or sham-hepatectomy rat liver cells had no significant effect. Twelve-hour conditioned media from regenerating liver cells, when added to normal hepatocyte cultures, produced significant ($p<0.001$) stimulation of ornithine decarboxylase activity 4 hr later. These studies suggest that the hepatocytes derived from the regenerating liver remnant secrete a factor(s) into the culture medium that produces stimulation of the rate of thymidine incorporation into DNA.

5952 INTEGRATED STEREOLOGICAL AND BIOCHEMICAL STUDIES ON HEPATOCYTIC MEMBRANES. I. MEMBRANE RECOVERIES IN SUBCELLULAR FRACTIONS.

(Eng.) Bolender, R. P.; Paumgartner, D.; Losa, G.; Muellener, D.; Weibel, E. R. (Dept. Biological Structure, Univ. Washington, Seattle, WA 98195). *J. Cell Biol.* 77(2):565-583; 1978.

A stereological study was undertaken to estimate membrane surface areas in the intact tissue, homogenate, and fractions of the same rat livers and then to test the comparability of these data with membrane marker enzymes by calculating both morphological and biochemical recoveries. The stereological data were corrected for errors due to section thickness and compression. The average total membrane surface area per gram of liver was 9.3 m^2 in the intact tissue (T), 7.8 m^2 in the homogenate (H), and 7.4 m^2 in the fractions (F); recoveries for the membrane surface areas thus averaged 96% for the (F/H) and 81% for the (F/T) comparisons. In homogenate and fractions, the differentiability of membranes by morphological criteria was limited to rough- and smooth-surfaced membranes, as well as outer and inner mitochondrial membranes. The recoveries of rough-surfaced membranes were 101% for F/H and 92% for F/T; those of smooth-surfaced membranes were 89% for F/H and 107% for F/T. For mitochondrial membranes, a recovery of 100% for F/H was obtained, whereas it amounted to only 54% for F/T. With respect to F/H, the membrane recoveries compare well with the marker enzyme recoveries obtained biochemically. The extension of recovery calculations to the intact tissue (F/T) revealed satisfactory conservation of the procedures of homogenization and fractionation; it indicates, however, that a shift of a substantial part of mitochondrial membranes to the pool of unidentifiable smooth membranes may occur on homogenization.

5953 TECHNIQUES FOR ASSESSMENT OF BILIARY EXCRETION AND ENTEROHEPATIC CIRCULATION IN THE RAT.

(Eng.) Johnson, P.; Rising, P. A. (Hoechst Pharmaceutical Res. Lab., Walton Manor, Walton, Milton Keynes MK7 7AJ, England). *Xenobiotica* 8(1): 27-36; 1978.

Surgical cannulation of the bile duct of rats (Charles River, Sprague-Dawley, CD, and Wistar) was performed to permit analysis of compounds excreted in the bile, and a modification of the procedure is also described for assessment of the reabsorption and recirculation of biliary excreted compounds. The bile duct was cannulated proximal to the liver (approximately 2 cm) to prevent admixture of pancreatic juice with the bile, which was continuously collected in a glass vessel inserted into the peritoneal cavity. After at least 16 hr, with addition of glucose to the drinking water and communal housing, the rats recovered, i.e. their activity, food and fluid intake, and defecation were normal. It was determined that 6-10 ml bile/100 g body weight/24 hr should be collected when the procedure is successful. The four ^{14}C-labeled compounds (Fendosal, Isoxepac, C 72 0045, and HP 505) that were administered p.o. and i.p. in various doses to test the efficacy of the method were recovered at rate of >95% in all but a single case. Bile may be collected for up to 6 days after dosing. For use of the procedure to determine enterohepatic recirculation, a second cannula was used to infuse bile collected from a donor rat into the duodenum. Poor recoveries in total reactivity were attributed to the use of a restraining cage, which was deemed inadequate for collection of urine and feces; however, calculations are presented that allow good agreement between experimental values and values for combined biliary/urinary reabsorption The specific metabolic distribution before and after recirculation was determined by thin-layer chromatography. This technique of assessing biliary excretion and recirculation is quick, simple, gives a comprehensive profile, and has the major advantage of maintaining nearly normal experimental conditions because the rats remain mobile after the operation.

5954 LIVER SUPPORT SYSTEMS: THE LOW CLEARANCE OF MODEL HEPATIC EXCRETORY ANIONS BY CHARCOAL HEMOPERFUSION.

(Eng.) Hew, J. T.; Hart, F. E.; Willson, R. A. (Div. Gastroenterology, Univ. Washington, Seattle, WA). *Gastroenterology* 74(4): 661-663; 1978.

Because the adsorptive properties of charcoal are complex and its systematic evaluation for the removal of model compounds from plasma is not complete, the clearance of strongly protein-bound cholephilic anions was assessed by measuring the removal of unconjugated bilirubin, BSP, and indocyanine green (ICG) by charcoal hemoperfusion in normal dogs. None of these model excretory compounds was effectively removed by the charcoal columns. *In vitro* studies of BSP and ICG suggested that poor removal of the anions was related to albumin binding in that, when the anions were in molecular solution, their extraction by the charcoal column was high (extraction ratios of 0.92 and 0.79, resp.), whereas, when albumin was added, their extraction was negligible (extraction ratios of 0.06 and 0.10, resp.). Therefore, if the removal from plasma of strongly bound toxins is important in the treatment of acute hepatic failure, additional support devices may have to be encompassed into the ultimately successful hepatic support system.

5955 LACTATE-STIMULATED ETHANOL OXIDATION IN ISOLATED RAT HEPATOCYTES. (Eng.) Crow, K. E.; Cornell, N. W.; Veech, R. L. (Dept. Chemistry, Biochemistry, and Physics, Massey Univ., Palmerston North, New Zealand). *Biochem. J.* 172(1):29-36; 1978.

The mechanism of lactate stimulation of ethanol oxidation was investigated. Hepatocytes isolated from starved rats and incubated without other substrates oxidized ethanol at a rate of 0.8-0.9 μmol/min/g wet weight of cells. Addition of 10 mM lactate increased this rate twofold. Quinolinate (5 mM) or tryptophan (1 mM) decreased the rate of gluconeogenesis with 10 mM lactate and 8 mM ethanol from 0.39 to 0.04-0.08 μmol/min/g wet weight of cells, but rates of ethanol oxidation were not decreased. It appears that acceleration of ethanol oxidation by lactate is not dependent upon the stimulation of gluconeogenesis and the consequent increased demand for ATP. As another test of the relationship between ethanol oxidation and gluconeogenesis, the initial lactate concentration was varied from 0.5 mM to 10 mM, and pyruvate was added to give an initial [lactate]/[pyruvate] ratio of 10. This substrate combination gave a large stimulation of ethanol oxidation (from 0.8 to 2.6 μmol/min/g wet weight of cells) at low lactate concentrations (0.5-2.0 mM), but rates remained nearly constant (2.6-3.0 μmol/min/g wet weight of cells) at higher lactate concentrations (2.0-10 mM). In contrast, owing to the presence of ethanol, the rate of glucose synthesis was only slightly increased (from 0.08 to 0.12 μmol/min/g wet weight of cells) between 0.5 mM and 2.0 mM lactate and continued to increase (from 0.12 to 0.65 μmol/min/g wet weight of cells) with lactate concentrations between 2 and 10 mM. In the presence of ethanol, O_2 uptake increased with increasing substrate concentration over the entire range. Changes in concentrations of glutamate and 2-oxoglutarate closely paralleled changes in the rate of ethanol oxidation. In isolated hepatocytes, rates of ethanol oxidation are lower than those *in vivo*, apparently because of depletion of malate-aspartate shuttle intermediates during cell preparation. Rates are returned to those observed *in vivo* by substrates that increase the intracellular concentration of shuttle metabolites.

5956 ENDOGENOUS AND EXOGENOUS HEPTADECAPEPTIDE GASTRIN TRANSPORT ACROSS THE PIG LIVER. (Eng.) Vinik, A. I.; Hickman, R.; Grant, B. J. (Dept. Medicine, Univ. Cape Town, Cape Town, South Africa). *S. Afr. Med. J.* 53(19):759-765; 1978.

Gastrin transport across the pig liver was studied in the basal unstimulated state and after infusions of exogenous synthetic human gastrin. *In vivo* studies showed no net loss or gain of endogenous porcine gastrin during transport across the liver in fasting animals. Infusion of synthetic human heptadecapeptide gastrin (G-17, 0.25, 0.5, and 1.0 μg/kg/min) raised circulating gastrin levels to those found in the postprandial state. At no time was there a loss or gain of immunologically determined gastrin across the liver. Changes in the molecular size of gastrin, however, suggest that qualitative but not quantitative effects followed the administration of G-17 *in vivo*. The disappearance of gastrin from the circulation was biphasic, with an initial half-life of 3 min and a slower phase suggesting recirculation or multicompartment equilibration. The distribution at equilibrium was ±20% of body weight calculated from arterial levels, but 30-40% if portal or hepatic venous values were used. The mean blood production rate was ±125 μg/day, but the portal contribution was only 30 μg/day, suggesting an important alternative source of gastrin. It is concluded that the liver plays an unimportant role in the inactivation of immunoreactive G-17 gastrin.

5957 REGULATION OF HEPATIC SYNTHESIS OF PROTEINS BY THE CHRONOLOGY OF PROTEIN INGESTION. (Eng.) Lardeux, B.; Bourdel, G.; Girard-Globa, A. (Centre de Recherches sur la Nutrition du C.N.R.S., 9, rue Jules Hetzel, 92 190 Meudon-Bellevue, France). *Biochim. Biophys. Acta* 518(1):113-124; 1978.

To assess the direct influence of protein ingestion on protein synthesis, circadian variations in liver protein synthesis were assessed in control rats fed a mixed 10% protein diet and in rats fed proteins as a separate meal either at 09:00 (SF 09) or at 21:00 (SF 21) and provided with a protein-free diet *ad libitum*. Protein synthesis was measured by incorporation of labeled leucine over 15 min at timepoints regularly spaced over 24 hr. In controls, the circadian variations observed were of moderate amplitude (from 2.75 mg/hr/g at 09:00 to 5.77 mg/hr/g at 06:00) and correlated with increased protein and RNA contents of the liver. In separately fed animals, ingestion of the protein meal triggered a 300% increase in protein synthesis within 1 hr while the feeding pattern was unaltered. In the SF 09 group, high synthetic activity was not followed by an increase of hepatic protein content, while hepatic urea concentrations were sharply increased (40-100% above the 24-hr mean) and glucogenic amino acid pools were greatly depleted (-25% at 0.5 hr after the meal). It is suggested that the high influx of amino acids consecutive to the absorption of the dietary proteins is the key factor stimulating protein synthesis, while synchronization with the energetic metabolism controls the degree of degradation.

5958 REPLACEMENT OF THE EXTRAHEPATIC COMMON BILE DUCT IN THE DOG BY AN ELASTOMERE SILICONE PROSTHESIS: POSSIBLE APPLICATIONS IN BILIARY SURGERY. (Fre.) Kron, B. (Clinique Chirurgicale de Sartrouville, 20, avenue Maurice-Berteaux, 78500 Sartrouville, France). *J. Chir. (Paris)* 114(4):237-256; 1977.

A method of replacing the common bile duct with a silicone elastomere prosthesis was studied in 21 dogs. A sutureless, double intubation technique was used to replace a 4-cm length of the common bile duct with the silicone tube. One postoperative death was caused by the intraperitoneal migration of the prosthesis. The other animals remained in excellent health with no signs of hepatic or biliary dysfunction for up to 2.5 years, except for two dogs who showed severe digestive problems 3 and 6 months after surgery, resp. Autopsies showed minimal hepatic lesions in one dog and a beginning cirrhosis in the other. Radiological and biological parameters were normal in all but the latter two dogs and one other with a dilatation of the common bile duct. The prosthesis could be easily removed after 6 months by a simple short choledochotomy, leaving a patent, permeable neocholedochus with excellent function. These good results suggest the use of this prosthesis in man for stenosis or operative wounds of the bile ducts, using either a removable tutor prosthesis or a segmental prosthesis lost internally. In palliative surgery for biliary carcinoma, the prosthesis can bypass the diseased ducts and be implanted in the stomach, duodenum, or jejunum; it is eliminated internally. It should also be possible to use a silicone prosthesis in certain cases of congenital bile duct abnormalities.

5959 EFFECT OF AGING ON BILIARY LIPID COMPOSITION AND BILE ACID METABOLISM IN NORMAL CHILEAN WOMEN.

(Eng.) Valdivieso, V.; Palma, R.; Wunkhaus, R.; Antezana, C.; Severin, C.; Contreras, A. (Universidad Catolica de Chile, Escuela de Medicina, Marcoleta 347, Santiago, Chile). *Gastroenterology* 74(5, Part 1):871-874; 1978.

To determine the effects of age and of obesity on biliary lipid composition and bile acid metabolism, biliary lipid composition was determined in fasting gallbladder bile of 12 young (16-25 yr) and 12 elderly (>50 yr) asymptomatic Chilean women with normal weights and recent, normal cholecystograms and in four elderly, obese women with radiologically normal gallbladders. The proportion of biliary cholesterol and the lithogenic index were significantly higher in the 12 asymptomatic elderly women of normal weight than in the young women (6.9 ± 1.8% versus 10.6 ± 2.9% cholesterol, $p<0.001$; lithogenic index 0.72 ± 0.19 versus 1.07 ± 0.28, $p<0.001$). Moreover, supersaturated bile was present in 8.3% of the young and in 41.7% of the older women studied. Obesity was found to enhance the saturation of bile in older females: lithogenic bile was found in all four elderly, obese women. The bile acid pool and cholic acid metabolism were studied in five young and four older normal women. Both groups showed similar values of bile acid pool, cholic acid synthesis, and turnover. These results indicate that aging *per se* modifies the proportions of biliary lipids in Chilean women, and provide a partial explanation for the frequency of gallstones observed among them. The increment in the lithogenic index of gallbladder bile with age takes place without significant changes in bile acid metabolism, suggesting that the canalicular secretion of cholesterol increases with aging.

5960 THE HEPATOTOXICITY OF 3-AMINO-1,2,4-TRIAZOLE AND CARBON DISULPHIDE IN PHENOBARBITONE-TREATED STARVED RATS.

(Eng.) Magos, L.; Butler, W. H.; Snowden, R. (Medical Res. Council Toxicology Unit, Carshalton, Surrey, England). *Toxicology* 9(1/2):103-107; 1978.

Experiments were carried out in phenobarbitone-treated Porton-Wistar rats to determine if aminotriazole is hepatotoxic in phenobarbitone-induced animals, and to see whether, under the same experimental condition, it interferes with the hepatotoxic effect of CS_2. In phenobarbitone-treated (80 and 50 mg/kg at 0 and 6 hr, resp., i.p.) starve male Porton-Wistar albino rats, 3-amino-1,2,4-triazole (1 g/kg, i.p.) produced moderate liver necrosis and increased the SGPT activity. If the animals were exposed for 4 hr to 2.0 mg/l CS_2, beginning 0.5 hr after aminotriazole administration the necrotic damage in the liver was larger and the SGPT activity higher than in rats not exposed to CS_2 ($p<0.001$). CS_2 in phenobarbitone-treated starved male rats caused only a very slight increas in the serum transaminase activity in spite of the widespread hydropic degeneration in the liver. These experiments indicate that an increase in serum transaminase activity is the consequence of necrosis and not of hydropic degeneration; aminotriazole is hepatotoxic in rats when microsomal enzymes are induced, and the separate hepatotoxicities of aminotriazole and of carbon disulfide are potentiated by the administration of the other compound.

5961 EFFECTS OF AUREOMYCIN ON BILE ACIDS IN RATS.

(Eng.) Madsen, D. C.; Wostmann, B. S.; Beaver, M.; Chang, L. (Lobund Lab., Univ. Notre Dame, Notre Dame, IN 46556). *J. Lab. Clin. Med.* 91(4):605-611; 1978.

To study the effect of antibiotics on the extent to which bile acids (BAs) are altered by bacteria, rats were treated for 5 days with low levels of Aureomycin (0.85 μM) in the drinking water. This treatment led to a predominance of ω-muricholic ac (ω-MC) over hyodeoxycholic acid (HDC) in the feces at 10 days after withdrawal of the antibiotic. Th reduced the usual HDC/ω-MC ratio from approximatel 2.0 to 0.9 or less. These rats were also found to have liver cholesterol levels modestly elevated over those of controls. In other experiments, the decrease in the HDC/ω-MC ratio was found to persis for at least 90 days after discontinuation of trea ment. Later experiments carried out with Aureomycin and with penicillin revealed the possible existence of a resistance factor to Aureomycin. A significant lowering of the HDC/ω-MC ratio was now found only with antibiotic concentrations 10 to 100 times greater than those used previously. Possible implications of the persistence of antibioti effects, as measured by changes in fecal BAs, include effects on vitamin metabolism, colon cancer, and cholesterol metabolism.

5962 THE EFFECT OF ADDED BRAN TO THE DIET ON THE SATURATION OF BILE IN PEOPLE WITHOUT GALLSTONES.

(Eng.) Watts, J. McK.; Jablonski, P. Toouli, J. (Flinders Medical Center, Bedford Park, South Australia 5042, Australia). *Am. J. Surg.* 135 (3):321-324; 1978.

To determine whether an increase in dietary fiber may create conditions in the biliary tract in which gallstones are less likely to form, bran was added to the diet of 11 volunteers without gallstones, and its effect on bile saturation, bile acid profile in bile, and serum cholesterol and triglycerides was determined. Bile cholesterol saturation was decreased after 2 months of feeding bran to those five women who had supersaturated bile (i.e., 1 saturation index). Bran may be effective in decreasing the lithogenic potential of bile in people without gallstones, and further studies on its place in the prevention of gallstones in susceptible individuals are indicated.

5963 REVERSAL OF CLOFIBRATE-INDUCED CHOLESTEROL OVERSATURATION OF BILE WITH CHENODEOXYCHOLIC ACID.

(Eng.) Bateson, M. C.; Ross, P. E.; Murison, J.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee DD1 9SY, Scotland). *Br. Med. J.* 1(6121):1171-1173; 1978.

Studies were carried out to assess whether the increase in biliary cholesterol induced by clofibrate is sustained and, if so, whether it can be reversed by chenodeoxycholic acid (CDCA) without any deterioration in the control of hyperlipemia. Giving clofibrate (2 g/day) to seven patients significantly increased the biliary cholesterol conentration ($p<0.05$) while the proportion of bile cids fell. Five patients on established clofirate treatment were given 750 mg of CDCA daily or 1 month. Biliary lipid analysis after the DCA treatment showed a significant fall in the roportion of cholesterol ($p<0.025$) and a rise in hat of bile acids ($p<0.01$). The serum lipid conentrations, which had already been reduced by diet nd clofibrate, showed a further significant reuction after the introduction of CDCA. This study uggests that CDCA may be usefully combined with lofibrate to reverse the tendency towards choleserol saturation of bile and enhance the effect of owering serum lipid concentrations.

964 LIVER DAMAGE IN RABBITS FROM ADMINISTRATION OF A SINGLE DOSE OF GRAM-NEGATIVE NDOTOXIN.

(Eng.) Aballi, A. J.; Karayalcin, G.; ostales, F.; Gubernick, I.; Lanzkowsky, P. (Long sland Jewish-Hillside Medical Center, New Hyde ark, NY 11040). *Pediatr. Res.* 12(5):646-651; 1978.

he effect of a preparatory dose of gram-negative ndotoxin on the liver was investigated, since epatic pathology may explain some disturbances roduced by endotoxin. Sixteen adult male New ealand rabbits had initial liver biopsies, blood hemistries, and coagulation studies and were then ivided into two groups: group I (10 animals) reeived 50 μg/kg endotoxin from *Escherichia coli* 111B4; group II (6 animals) served as controls nd received no endotoxin. In group I, all animals eveloped increased levels of LDH isoenzyme 5 and GOT and decreased serum albumin levels. A rise in the level of SGPT and 5'-nucleotidase occurred in most rabbits. LDH isoenzyme 5 values increased from 3.6 ± 5.83 mU/ml before to 180.4 ± 142.11 mU/ml after endotoxin ($p<0.005$). SGOT levels rose from 28.90 ± 8.87 mU/ml to 241.10 ± 104.76 mU/ml ($p<0.001$). Serum albumin levels decreased from 3.78 ± 0.31 g/dl to 3.21 ± 0.32 g/dl ($p<0.001$). SGPT levels initially showed a level of 41.00 ± 6.97 mU/ml, which rose to 94.40 ± 19.60 mU/ml ($p<0.001$). 5'-Nucleotidase levels rose from 1.48 ± 0.69 mU/ml to 6.01 ± 4.51 mU/ml ($p<0.01$). The animals also had changes in coagulation tests, with a decrease in factors II and V. Factor II was 77.4 ± 11.82% before and 38.70 ± 7.47% after endotoxin ($p<0.001$). Factor V values were 95.00 ± 9.04% before and 50.6 ± 7.5% after endotoxin ($p<0.001$). Changes in fibrinogen and factor VIII levels were not significant. Split products of fibrinogen showed a slight increase. Definite hepatic necrosis consisting of scattered patchy areas of variable size and severity was found in 7 of the 10 animals. In many of these areas of necrosis, a polymorphonuclear leukocyte reaction and a few small thrombi were detectable. The liver biopsies performed before endotoxin administration failed to show any evidence of hepatic involvement. Group II controls showed no indications of abnormal liver function and no evidence of hepatic necrosis. These studies indicate that significant hepatic changes occur after the administration of a single dose of endotoxin given in preparation for the Shwartzman reaction.

5965 EFFECT OF SINUSOIDAL PERFUSION ON GALACTOSE ELIMINATION KINETICS IN PERFUSED RAT LIVER.

(Eng.) Keiding, S.; Chiarantini, E. (Rigshospitalet, Copenhagen, Denmark). *J. Pharmacol. Exp. Ther.* 205(2):465-470; 1978.

A model that assumes the elimination of substrates from the blood by the intact liver to take place at a sinusoidal concentration decreasing along the flow (sinusoidal perfusion model) was evaluated and compared with an earlier approach assuming the elimination to take place at the outflow concentration. Ten livers from female Wistar rats (average weight, 200 g) were perfused in a recirculating system. The rats had been starved for 18 hr prior to perfusion and a constant galactose elimination rate was ensured by constant galactose infusion. Each experiment consisted of three steady-state periods with a blood flow of 15, 9, and 15 ml/min, resp. The sinusoidal perfusion model predicts that reduction of flow at a given elimination rate will reduce hepatic outflow concentration, in contrast to the other model that predicts the outflow concentration to be constant. According to the sinusoidal perfusion model, the logarithmic average concentration ($\hat{c}$) is independent of flow at a given elimination rate; $\hat{c}=(c_i-c_o)/\ln(c_i/c_o)$, where c_i is the inflow concentration and c_o the outflow concentration. There was a significantly lower outflow concentration during the period with low flow than during periods with high flow ($p<0.01$), whereas the logarithmic average concentration was not changed. These observations are consistent with the sinusoidal perfusion model but do not comply with the earlier proposed use of the outflow concentration as an approximation to the sinusoidal concentration.

5966 BIOACTIVATION AND COVALENT BINDING OF HALOTHANE TO LIVER MACROMOLECULES.

(Eng.) Sipes, I. G.; Podolsky, T. L.; Brown, B. R., Jr. (Health Sciences Center, Univ. Arizona, Tucson, AZ 85724). *Environ. Health Perspect.* 21:171-178; 1977.

Studies were carried out in rats to determine if ^{14}C-halothane or its metabolites interact with DNA. Three bioactivation systems were used: *in vitro* microsomal incubations, isolated hepatocytes, and *in vivo* administration. Even though optimal conditions for bioactivation were used, no significant covalent binding of ^{14}C to DNA was observed. Slight ^{14}C activity above background (6 disintegrations/min/0.1 mg DNA) was observed in the microsomal incubations but was considered insignificant because it was not reduced when NADPH was omitted from the incubations. Covalent binding to nuclear lipids and proteins was observed when rats were pretreated with phenobarbital and maintained in a hypoxic environment (14% O_2). Similarly, these conditions markedly increased covalent binding of ^{14}C from ^{14}C-halothane to microsomal proteins and lipids. Isolated rat hepatocytes proved to be a viable system for studying the bioactivation of halothane. In this system it was also possible to demonstrate increased binding under N_2 and/or phenobarbital pretreatment.

5967 HALOTHANE HEPATOTOXICITY AND THE REDUCED DERIVATIVE, 1,1,1-TRIFLUORO-2-CHLOROETHANE.

(Eng.) Brown, B. R., Jr.; Sipes, I. G.; Baker, R. K. (Univ. Arizona Coll. Medicine, Tucson, AZ 85724). *Environ. Health Perspect.* 21:185-188; 1977.

Studies were carried out to investigate the mechanism by which 1,1,1-trifluoro-2-bromo-2-chloroethane (halothane) produces hepatic necrosis. Since the bonding energy of the bromine atom in halothane is known to be relatively weak, the possibility that an enzymatic reductive attack could occur at this site was investigated by synthesizing and studying the hepatotoxic potential of the reduced, debrominated product of halothane, 1,1,1-trifluoro-2-chloroethane. The derivative was unstable and thus was prepared anaerobically and trapped in propylene glycol solvent. Approximately 1 mg of 1,1,1-trifluoro-2-chloroethane in 0.5 ml solvent was injected into the portal vein of male Sprague-Dawley rats under pentobarbital anesthesia (25 mg/kg). The rats were sacrificed 24 hr later. This treatment produced extensive liver necrosis, whereas treatment with the vehicle alone was innocuous. It is postulated that biotransformation of halothane via a reductive pathway could produce this reactive intermediate metabolite, resulting in the hepatotoxicity of this anesthetic.

5968 BILE FLOW AND BILIARY EXCRETION RATE OF SOME ORGANIC ANIONS IN PHENOBARBITAL-PRETREATED RATS.

(Eng.) Fischer, E.; Varga, F.; Gregus, Z.; Gogl, A. (Univ. Medical Sch. Pecs, Szigeti u. 12, H-7643 Pecs, Hungary). *Digestion* 17(3):211-220; 1978.

To gain more information on the correlation between the choleretic effect and the increased biliary excretion in phenobarbital-pretreated rats, bile flow and the biliary excretion of indocyanine green, bromcresol green, eosine, BSP-glutathione conjugate (BSP-GSH), amaranth, and iodoxamic acid were investigated in control and phenobarbital-pretreated rats (75 mg/kg/day, i.p., for 5 days). The bile flow was increased by phenobarbital from an average of 50.6 to 77.7 µl/kg/min. Depending on the dose, the biliary excretion rate of bromcresol green was increased by 48-496% and that of eosine by 30-149%. After phenobarbital pretreatment, the excretion of BSP-GSH was also enchanced by 34-52%, that of amaranth by 37-53%, and that of iodoxamic acid by 40-56%. However, the biliary excretion of indocyanine green remained unchanged. There was no parallelism between the increase in bile flow and biliary excretion of the drugs.

5969 CHOLESTEROL IN ACUTE CHOLESTASIS INDUCED BY TAUROLITHOCHOLIC ACID: A CYTOCHEMICAL STUDY IN TRANSMISSION AND SCANNING ELECTRON MICROSCOPY.

(Eng.) Bonvicini, F.; Gautier, A.; Gardiol, D.; Borel, G. A. (Istituto di Patologia Speciale Medica, Universita degli Studi di Chieti, I-60100 Chieti, Italy). *Lab. Invest.* 38(4):487-495; 1978.

Studies were carried out to verify that ultrastructural changes of taurolithocholic acid-induced cholestasis are similar to those in cholestasis produced by other bile acids or their sodium salts and to correlate chronologically these modification with the variations in bile flow. In addition, attempts were made to determine the cytochemical nature of the substances responsible for the development of these crystalline structures, with particular emphasis on the role of free cholesterol in this process. Rats were each given a single i.v dose of sodium taurolithocholate (100 mg/kg), and an almost total cholestasis appeared after 10 min and lasted for 3 hr after the injection; then choleresis began again, and 24 hr after the injection, normal values of bile flow were restored. Ultrastructural analysis of the liver during the acute cholestasis and the restoration phase showed, beside usual modifications found in most cases of cholestasis, the "characteristic" alterations of sodium taurolithocholate-induced cholestasis. Afte Williamson's reaction procedure, not only were cholesterol-digitonin complexes found in large numbers both in the hepatocytic cytoplasm and in the biliary canaliculi, but also their morphologic appearance revealed several new features: dark sticks and dark lamellae, frequently adsorbed on the outer surface of crystalline clear material, were observed by transmission electron microscopy and plugs, obliterating parts of biliary canaliculi were observed using scanning electron microscopy. These observations seem to indicate that a significant amount of free cholesterol is released into

he hepatocyte cytoplasm and into canalicular lu-
ina within a few minutes after the injection of
odium taurolithocholate, probably originating
rom the hepatocytic membranes, especially from
hose limiting the canalicular lumen. Such a
rastic modification in the chemical constitution
f these membranes should coincide with a marked
odification of their active and passive transport
bility.

970 FATTY LIVER IN HYPERVITAMINOSIS A: SYNTHESIS AND RELEASE OF HEPATIC TRIGLYCER-
DES. (Eng.) Singh, M.; Singh, V. N. (Vallabhbhai
atel Chest Inst., Univ. Delhi, Delhi, 110007 In-
ia). *Am. J. Physiol.* 234(5):E511-E514; 1978.

tudies were carried out in rats to determine the
ffect of excessive vitamin A intake on hepatic
riglyceride secretion into plasma. Feeding large
oses (30,000 IU/100 g body weight/day) of vitamin
to young rats for 2 days produced fatty liver,
aused a stimulation of oxidation ($p<0.001$) and
sterification ($p<0.01$) of [1-^{14}C]palmitate by
iver slices, and increased the activity of hepatic
almitoyl-coenzyme A synthetase ($p<0.01$). Under
imilar conditions, however, release of hepatic
riglycerides into the plasma, as judged from the
ost-Triton triglyceridemia, remained unaffected.
hese findings indicate that excessive vitamin A
ntake produces fatty liver by stimulating the
ynthesis of triglycerides in liver without af-
ecting the rate of secretion of hepatic triglycer-
des. An involvement of altered oxidation of fatty
cids in the liver can also be ruled out, because,
n hypervitaminosis A, this process is increased
ather than decreased as required for fatty liver
roduction.

971 IMPROVED HEPATIC FUNCTION AND SURVIVAL WITH ADENOSINE TRIPHOSPHATE-MAGNESIUM
HLORIDE AFTER HEPATIC ISCHEMIA. (Eng.) Hirasawa,
.; Chaudry, I. H.; Baue, A. E. (Yale Univ. Sch.
edicine, 333 Cedar St., New Haven, CT 06510).
urgery 83(6):655-662; 1978.

he effect of infusion of ATP-MgCl$_2$ after 60 or 90
in of total hepatic ischemia was studied, since
revious work had shown a protective effect of the
dministration of this complex in postischemic
cute renal failure and shock. Following the re-
ease of the hepatic vascular occlusion, ATP-MgCl$_2$,
TP alone, or MgCl$_2$ alone (0.25 ml, 12.5 μmol
ach) was given i.v. to treated animals, and saline
0.25 ml) was given to the controls. Survival was
easured over a period of 5 days. The survival
ate after 60 and 90 min of ischemia was 87.5% and
9.2% in the ATP-MgCl$_2$-treated animals and 43.8% and
3.1% ($p<0.01$ at 60 min and $p<0.02$ at 90 min) in
he control group, resp. When either ATP or MgCl$_2$
lone was given after 60 min of hepatic ischemia,
he survival rate was 20% and 30%, resp. In another
roup of animals, serum enzyme and hepatic ATP lev-
ls were measured 1 hr following the release of 60
in of ischemia. SGOT and SGPT levels were greatly
ncreased following ischemia (1,976 ± 176 and
,141 ± 111 IU/l, resp., after 60 min of ischemia),
d the levels of these enzymes were significantly lowered (729 ± 96 and 520 ± 127 IU/l, resp., $p<0.001$) with ATP-MgCl$_2$ treatment. Hepatic cellular ATP levels and energy charge were significantly decreased during occlusion (1.20 ± 0.11 μmol/g); however, ATP levels were increased (1.87 ± 0.1, $p<0.001$) and the energy charge returned to normal following ATP-MgCl$_2$ treatment. Thus, increased survival and improved hepatic function after ischemia were associated with elevated cellular ATP levels following ATP-MgCl$_2$ administration. While the precise mechanism of action of ATP-MgCl$_2$ remains unknown, these observations may have important implications for future use in organ preservation, management of postischemic acute hepatic failure, and multiple systems failure.

5972 POLYVINYLCHLORIDE (PVC) PARTICLES IMPLANTATION IN MOUSE LIVER. A TECHNIQUE FOR EXPERIMENTAL STUDY OF SCHISTOSOME EGGS-INDUCED LIVER PATHOLOGY. (Eng.) Joky, A.; Cornu, M.; Louis, D.; Grimaud, J. A. (Centre de Microscopie Electronique et de Pathologie Ultrastructurale, Institut Pasteur, 77, rue Pasteur, F-69265 Lyon, France). *Experientia* 34(4):547-549; 1978.

To study the cellular changes of the portal tract produced by foreign body granuloma and the consequent hepatic vascular bed modifications, a model system was developed using intrahepatic implantation of polyvinylchloride (PVC) particles in Swiss albino mice. Five control mice, 10 mice injected into the cecal vein with PVC particles (about 20,000 particles each 110 ± 30 μm in diameter and 1.4 in density), and 5 mice infested with cercariae of *Schistosoma mansoni* were examined 8 days after injection or 8 weeks after cercarial exposure by light and electron microscopy and by the preparation of plastic casts of the portal system. The plastic casts revealed a marked decrease in the number of small injected veins and a sudden reduction in the diameter of the medium and small portal veins in the PVC-injected livers that was also apparent in the schistosome-infested livers as compared with the normal controls. Light microscopy revealed a granulomatous reaction around the PVC particles, and electron microscopy of periparticular granulomatous areas showed numerous macrophages and giant cells in contact with the PVC particles, and a lymphoplasmocytic, granulocytic, and fibroblastic infiltration was also evident. This technique produces changes in the intrahepatic portal system similar to those seen in human and murine schistosomiasis and appears useful to test the consequences of permanent portal foreign body modification on fibroblastic stimulation, collagen deposition, and fibrous tissue remodeling.

5973 INCREASED BILIRUBIN EXCRETION INTO BILE AFTER CHRONICAL [sic] CLOFIBRATE (C) ADMINISTRATION IN THE RAT [Abstract]. (Eng.) Kutz, K.; Schulte, A.; Fevery, J. (Medizinische Poliklinik, Univ. Bonn, Bonn, W. Germany). *Digestion* 16(4): 331; 1977.

Intestine

6006 DETERMINATION OF VIABILITY OF ISCHEMIC INTESTINE BY DOPPLER ULTRASOUND. (Eng.)

Cooperman, M.; Pace, W. G.; Martin, E. W., Jr.; Pflug, B.; Keith, L. M., Jr.; Evans, W. E.; *et al.* (Dept. Surgery, Ohio State Univ., Columbus, OH 43210). *Surgery* 83(6):705-710; 1978.

Experiments were carried out to determine whether Doppler ultrasound can be used to determine the viability of ischemic small intestine and to select the optimum point for resection of nonviable bowel. Twenty ischemic segments of small intestine were produced in dogs by ligating the vascular supply. The Doppler ultrasound probe then was used to determine the last point of arterial flow within the bowel wall. The dogs were re-explored after 24 hr. Histological examination of full-thickness biopsies showed the intestine to be normal in all 20 segments at the last audible Doppler signal, and in 19 of the 20 segments at 1 cm distal to the last signal. Progressive degrees of necrosis were observed at 2 and 3 cm distal to the last signal. Twenty-five segments of ischemic intestine were resected in baboons. All resections performed at the last Doppler signal or 1 cm distal to it were normal 1 month later. Of 15 resections performed at 2, 3, and 4 cm distal to the last signal, 10 showed evidence of stricture or anastomotic disruption. Doppler ultrasound is a reliable method for determining the viability of ischemic intestine and for selecting the optimum point for resection of nonviable bowel.

6007 REGULATION OF CHOLESTEROL SYNTHESIS IN CULTURED CANINE INTESTINAL MUCOSA.

(Eng.) Gebhard, R.•L.; Cooper, A. D. (Minneapolis Veterans Admin. Hosp., Minneapolis, MN 55417). *J. Biol. Chem.* 253(8):2790-2796; 1978.

The validity of the intestinal organ culture technique for investigating the regulation of intestinal cholesterol synthesis was examined and the effects of free cholesterol, oxygenated cholesterol derivatives, bile salts, and lipoproteins on this process were studied in canine ileal mucosa maintained in organ culture for 6 hr. Viability was monitored by light and electron microscopy, measurement of cellular enzymes, and the ability to actively transport a glucose analogue. The activity of 3-hydroxy-3-methylglutaryl coenzyme A (HMG-CoA) reductase, the rate-limiting enzyme of cholesterol synthesis, increased fourfold during the 6-hr culture. A parallel increase occurred in the rate of acetate incorporation into digitonin-precipitable sterols during this period. This increase was prevented by the addition of 0.2 mM cycloheximide to the culture. Pure colesterol, 7-ketocholesterol, and 25-hydroxycholesterol, when present at 0.2 mM during the last 4 hr of culture, also caused significant ($p<0.01$) suppression of the rise in HMG-CoA reductase activity (final HMG-CoA reductase with the three sterols was 77 ± 4%, 68 ± 5%, and 58 ± 3% of control postculture value, resp.). Bile salts at low, nontoxic concentratio also inhibited the increase of enzyme activity (2 taurocholate=63 ± 3% of control, 0.5 mM taurochenodeoxycholate=76 ± 6% of control). In contrast, dog lipoproteins separated by ultracentrifugation failed to significantly affect intestinal cholesterol synthesis in these short-term organ cultures. The intestinal organ culture technique is valid for measuring intestinal cholesterol synthesis. The suppression of cholesterol synthesis produced by the addition of cholesterol to the culture medium convincingly demonstrates that aut regulation can occur.

6008 CHYMOTRYPSINLIKE ACTIVITY OF SOME INTESTINAL BACTERIA. (Eng.)

Gyr, K.; Felse feld, O.; Imondi, A. R. (Kantonsspital, CH-4004 Basel, Switzerland). *Am. J. Dig. Dis.* 23(5):413-416; 1978.

Since some tests of exocrine pancreatic function are based on the estimation of intestinal chymotryptic activity by using specific substrates suc as *N*-benzoyl-L-tyrosyl-PABA (BT-P), the action of a number of bacteria isolated from human or monke intestines on BT-P was investigated. The monkeys studied had an intestinal flora closely resemblin that of man. Except for *Bacteroides*, *Proteus vulgaris* No. 73, *Proteus morgani* No. 202, and *Pseudomonas aeruginosa* No. 76, significant splitting of BT-P did not take place when 20 common enteric microorganisms were tested. It is concluded that with the possible exception of bacterial overgrow of the small bowel, microbial chymotryptic activi is not important in influencing the outcome of th BT-P test.

6009 POSTNATAL DEVELOPMENT OF CIRCADIAN RHYT IN DISACCHARIDASE ACTIVITIES IN RAT SMA INTESTINE. (Eng.)

Saito, M.; Sudo, M.; Matzuda, (Sch. Medicine, Ehime Univ., Shigenobu, Ehime 791-02, Japan). *Am. J. Physiol.* 234(5):E500-E503; 19

To examine the relationship between the disaccharidase activity rhythm and food intake during development, the circadian rhythms in the activitie of maltase and lactase of the small intestine wer examined at various stages of postnatal developme in rats. When the rats were fed *ad libitum*, no circadian change in the enzyme activities was fou during the suckling or the weanling period. However, approximately 1 week after the time of weaning, the enzymes showed the same circadian changes as in adult rats, with higher activities night ($p<0.001$, difference between maltase activi at 0000 and 1200 hr). After weaning, when the ra were fed only during the daytime, the phase of th enzyme rhythm shifted about half a day, and the highest activity was observed around feeding time However, during the suckling period, no circadian rhythm in the enzyme activities was found, even when the rats were allowed to feed only during a

estricted time of the day. The authors postulate
hat the postnatal development of the enzyme activ-
ity rhythm may depend on maturation of a mechanism
hat is based on the rats' anticipating daily feed-
ing; if this is so, this anticipatory mechanism has
ot yet developed during the suckling period.

010 SUBCELLULAR LOCALIZATION OF ENTEROKINASE IN HUMAN DUODENAL MUCOSA. (Eng.) Lobley,
. W.; Franks, R.; Holmes, R. (Manchester Royal In-
irmary, Oxford Rd., Manchester M13 9WL, England).
lin. Sci. Mol. Med. 53(6):551-562; 1977.

o determine whether the brush border is the only
ubcellular locus of enterokinase activity, the
ocalization of enterokinase was studied in human
uodenal mucosa, using a subcellular fractionation
echnique whereby the principal organelles of the
nterocyte could be separated with minimal damage,
nd the overall subcellular distribution of the
nzyme determined. Specimens of mucosa were ob-
ained at duodenotomy. Superficial mucosal scrap-
ngs were homogenized in isotonic sucrose solution
nd fractionated by differential centrifugation.
he distribution of organelles among the subcellular
ractions was monitored by assay of suitable marker
nzymes. Enterokinase was recovered predominantly
n the nuclear and brush border fraction, and 80%
f the total activity was found to be particulate;
pproximately 20% of the enzyme was present in the
oluble fraction, compared with 1% of the brush
order markers sucrase and alkaline phosphatase.
he brush border-containing fraction was subfraction-
ted by treatment with hypertonic Tris followed by
ifferential and density gradient centrifugation.
nterokinase was distributed among the subfractions
n parallel with brush border markers and was con-
entrated in a subfraction that was highly en-
iched in microvillous membranes. It is concluded
hat enterokinase is localized primarily to the
icrovillous membrane of the epithelial cell brush
order in man, but that, in addition, a proportion
f the enzyme may be present in a soluble or easily
eleased form in the duodenal mucosa.

11 GLYCOPROTEIN CONTAINING VESICLES IN THE SURFACE EPITHELIAL CELLS OF THE ASCENDING
LON OF THE RAT. (Eng.) Michaels, J. E. (Univ.
incinnati, Coll. Medicine, Cincinnati, OH 45267).
at. Rec. 188(4):525-533; 1978.

e hypothesis that the glycoproteins of the cell
at are completed in the Golgi apparatus and mi-
ate to the cell surface in vesicles has been
pported by the results of radioautographic stud-
s in the ameba and in the mouse ascending colon,
d this theory was further investigated in a
rphological and cytochemical study of the surface
ithelial cells of the rat ascending colon. Fila-
ntous material, resembling the cell coat, was
en to be contained in saccules toward the mature
ce of the Golgi apparatus and in vesicles close
the apparatus and near the terminal web. The
sicles were limited by a unit membrane composed
asymmetric osmiophilic leaflets and similar to
e plasma membrane. When stained by the periodic acid-chromic acid-silver methenamine technique, silver was precipitated on the cell components containing the filamentous material, indicating the presence of glycoproteins. Narrow invaginations from the cell surface that may correspond to vesicles undergoing exocytosis were also positive for glycoproteins. The distribution of the filamentous material that was glycoprotein-positive parallels the pathway followed by material that had been found to be labeled with a tritiated glycoprotein precursor (^{3}H-fucose) in the epithelial cells of the ascending colon of the mouse. It is suggested that the system of vesicles in the rat colon cells is acting in a manner similar to the vesicles in the mouse cells to transport cell coat glycoproteins from the Golgi apparatus to the cell surface.

6012 STUDIES ON THE BRUSH BORDER MEMBRANE OF MOUSE DUODENUM: LIPIDS. (Eng.) Billington, T.; Nayudu, P. R. V. (Dept. Zoology, Monash Univ., Clayton, Victoria 3168, Australia). *Aust. J. Exp. Biol. Med. Sci.* 56(Part 1):25-29; 1978.

The types and quantities of lipids extracted from purified mouse duodenal brush border membranes were studied. Lipid:protein ratios in different membrane preparations varied from 0.58 to 0.68. Both the chloroform and non-chloroform phases were quantitatively analyzed for lipids. Chloroform extracts were composed of cholesterol, triglycerides, and phospholipids. The major neutral lipid was cholesterol. Rechromatography of the phospholipid spot showed sphingomyelin (7.9%), phosphatides of ethanolamine (61.7%), inositol (14.2%), and serine (16.2%). The average molar ratio of cholesterol to phospholipid was 1:39. Lipids in the non-chloroform phase were all glycosylated, being cerebrosides (69.3%), cerebroside sulfates (28.8%), and gangliosides (1.9%). Overall membrane lipid composition was neutral lipid 24%, phospholipid 33%, and glycolipid 43%. There are both quantitative and qualitative differences in the lipid composition of the brush border membranes of mouse and rat.

6013 LIPID SYNTHESIS IN ISOLATED INTESTINAL CELLS. (Eng.) Shakir, K. M. M.; Sundaram, S. G.; Margolis, S. (Johns Hopkins Sch. Medicine, Baltimore, MD 21205). *J. Lipid Res.* 19(4): 433-442; 1978.

Since the small intestine contributes significantly to serum cholesterol and very low density lipoprotein levels, acute regulation of lipid synthesis was investigated in isolated rat intestinal cells incubated in Krebs-Ringer bicarbonate buffer with 5 mM glucose and ^{14}C-acetate or $^{3}H_2O$ to test the suitability of this preparation for studying this phenomenon. Incorporation of ^{14}C-acetate into cellular lipids was six- to eightfold greater in crypt than in villus cells. In both cell types, the distribution of ^{14}C among the various lipid classes was as follows: 52.5% in triglycerides, diglycerides, and monoglycerides; 22.3% in cholesterol; 8.3% in cholesteryl esters; 1.9% in fatty acids; and 15.0% in phospholipids. In contrast, the lipids in the medium contained significantly higher ($p<0.001$ or $p<0.005$) amounts of tri-, di-, and monoglycerides (61.1%) and lower ($p<0.05$) amounts of cholesteryl esters (2.3%) and phospholipids (11.9%). After saponification, two-thirds of the recovered ^3H_2O was in fatty acids and one-third in cholesterol. Ethanol treatment (10 mM) tripled ^3H_2O incorporation into cellular lipids but had no effect on ^{14}C-acetate incorporation. Epinephrine and norepinephrine (10 μM), glucagon (10 μM), dibutyryl cyclic AMP (1 mM), dexamethasone (1 mM and 1 μM), and cholera toxin (1 μg/ml) did not affect ^{14}C-acetate incorporation. It is concluded that ethanol stimulates intestinal lipid synthesis; however, in sharp contrast to their inhibition of lipid synthesis in hepatocytes and adipocytes, catecholamines, glucagon, and dibutyryl cyclic AMP do not inhibit lipid synthesis in intestinal cells.

6014 RAT INTESTINE SECRETES DISCOID HIGH DENSITY LIPOPROTEIN. (Eng.) Green, P. H. R.; Tall, A. R.; Glickman, R. M. (Beth Israel Hosp., Boston, MA 02215). *J. Clin. Invest.* 61(2):528-534; 1978.

To determine whether mesenteric lymph contains nascent high density lipoprotein (HDL), HDL was isolated from pooled rat serum and mesenteric lymph of lymph fistula rats. In most experiments, 5,5'-dithionitrobenzoic acid, an inhibitor of the enzyme lecithin:cholesterol acyltransferase, was added during the collection of lymph to prevent modification of the lipid composition of newly secreted lipoproteins. Negative staining electron microscopy of lymph high density lipoprotein revealed discoidal particles (190 ± 3 x 55 ± 1 A) which tended to form rouleaux; smaller spherical particles were also present. Serum high density lipoprotein contained only spherical particles (diameter 93 ± 4 A). Lipid analysis showed that lymph HDL was enriched in phospholipid and deficient in cholesterol esters when compared with serum HDL. The phospholipid to cholesterol esters ratio was greatest in basal lymph HDL when compared with fatty lymph and serum HDL. From analysis of the lipid compositional data and direct particle measurement by electron microscopy, it was calculated that approximately 50% of basal lymph HDL and 30% of fatty lymph HDL was discoid. Basal lymph HDL was enriched in apoprotein A-I and deficient in the arginine-rich peptide, and the apoprotein composition of fatty lymph HDL more closely resembled that of serum. These observations demonstrate that intestinal lymph contains two types of HDL particles, a discoid nascent particle deficient in cholesterol ester and rich in apoprotein AI, and spherical HDL derived from plasma. A significant amount of lymph HDL appears to be secreted by the intestine.

6015 CONTRIBUTIONS OF BILE AND PANCREATIC JUICE TO CELL PROLIFERATION IN ILEAL MUCOSA. (Eng.) Williamson, R. C. N.; Bauer, F. L. R.; Ross, J. S.; Malt, R. A. (Shriners Burns Inst., Boston, MA). *Surgery* 83(5):570-576; 1978.

To determine the relative contributions of bile and pancreatic juice to adaptive intestinal hyperplasia cell proliferation in rat ileal mucosa was studied after supplying bile alone or the combined pancreaticobiliary effluent directly to the mid-small bowel. Bile was routed through the choledochus cannulated above the pancreas. Pancreaticobiliary secretions were diverted through a transposed duodena segment containing the papilla. Transection of the jejunum with reanastomosis was performed as a control operation. Diversion of bile into the midbowel with and without pancreatic juice caused similar increases in ileal RNA (16-50%) and DNA (22-41%) contents at both 48 hr and 1 week after operation. Specific activity of DNA after injection of tritiated thymidine was greatest after diversion of the combined effluent. After 1 month, nucleic acid contents in the upper ileum after pancreaticobiliary diversion were 37% to 59% higher than after transection or biliary diversion ($p<0.005$). Likewise, after biliary diversion villous height and crypt depth were increased only at 1 week, but after diversion of both secretions increases were found at 1 week and 1 month. High luminal concentrations of bile cause transient cell proliferation in ileal mucosa, but the additional presence of pancreatic juice prolongs this adaptive response

6016 LACK OF EFFECT OF BILE IN PATHOGENESIS OF SECRETION IN MECHANICAL SMALL BOWEL OBSTRUCTION. (Eng.) Mirkovitch, V.; Blanc, D.; Macarone-Palmieri, R.; Mosimann, F.; Robinson, J. W. L.; Menge, H. (Departement de Chirurgie Experimentale, CHUV, CH-1011 Lausanne, Switzerland). *Digestion* 17(3):204-210; 1978.

The role of stagnated bile as a possible agent provoking the intestinal secretion observed above a mechanical obstruction in dogs was explored by ligating the common bile duct and diverting the bil by means of an anastomosis between the gallbladder and the ileum distal to the obstruction. Seven days after the creation of an obstruction with bil diversion, the functional and morphological change in the obstructed loop were almost identical to those occurring in animals with obstructions without bile diversion. The secretory response above the obstruction continued unabated, with levels of cyclic AMP in the secreting mucosae lower than in control tissues. These results suggest that the secretion in the obstructed intestine is not influenced by the presence of bile, and that this secretion may not be secondary to an increase in mucosal cyclic AMP levels.

6017 PREVENTION AND REVERSAL OF CHOLERA ENTE TOXIN EFFECTS IN RABBIT JEJUNUM BY NICOTINIC ACID. (Eng.) Turjman, N.; Gotterer, G. S. Hendrix, T. R. (Johns Hopkins Univ. Sch. Medicine, Baltimore, MD 21205). *J. Clin. Invest.* 61(5):1155 1160; 1978.

Studies were carried out to determine whether intestinal secretion and cyclic AMP (cAMP) elevation induced by cholera toxin could be prevented, or once initiated, reversed by nicotinic acid, an gent known to lower tissue levels of cAMP. In abbits, four jejunal loops were constructed as lternating control (3-ml isotonic electrolyte olution) and cholera toxin (same solution containing 0 μg purified cholera toxin) loops. Net intestinal ecretion was determined by measuring fluid accum-lation, after which intestinal biopsies were taken or cAMP assay. The animals were pretreated either ith 50 mg/kg nicotinic acid in saline 3 hr and 1 r before the introduction of cholera toxin, or ntraluminally with 200 mg/kg nicotinic acid in inger's lactate solution 15 min before the instil-ation of cholera toxin. Under these conditions, icotinic acid blocked the cholera toxin-induced ecretion and the rise in cAMP measured 3 hr after he loops were exposed to cholera toxin. The ef-ect of the nicotinic acid administered within he lumen on net intestinal secretion was studied. aximal inhibition of net intestinal secretion was chieved with an intraluminally administered dose f nicotinic acid of 100 mg/kg. This dose was hosen for testing the ability of nicotinic acid o reverse the effects of cholera toxin. When icotinic acid was instilled into a fifth loop onstructed distally to the four experimental loops hr after exposure of these loops to cholera oxin, both intestinal secretion and elevation of AMP were reversed. These results suggest that icotinic acid can prevent and reverse the secre-ory effects of cholera toxin and may have a role n the therapy of cholera and other cAMP-associated iarrheal diseases.

018 INFLUENCE OF DIETS HIGH AND LOW IN ANIMAL FAT ON BOWEL HABIT, GASTROINTESTINAL TRAN-IT TIME, FECAL MICROFLORA, BILE ACID, AND FAT EX-RETION.

(Eng.) Cummings, J. H.; Wiggins, H. S.; enkins, D. J. A.; Houston, H.; Jivraj, T.; Drasar, . S.; *et al.* (Medical Res. Council Dunn Nutrition nit, Cambridge, England). *J. Clin. Invest.* 61(4): 53-963; 1978.

nder metabolic conditions, the effect of diets con-aining 62 or 152 g/day of fat mainly of animal origin n bowel habit, gastrointestinal transit time, fecal icroflora, bile acids, and fat excretion were inves-igated in six healthy young men over 4-week periods, n an effort to determine whether dietary fat could e responsible for slow transit and reduced fecal ulk, which has been associated with large bowel can-er. No change attributable to the diet was observed n the subjects' bowel habit, fecal weight, mean ransit time through the gut, or in the excretion f dry matter. Total fecal bile acid excretion as significantly higher on the high fat diet (320 120 mg/day) than on the low fat diet (139.7 ± 63 g/day, *t* test=7.78, $p<0.001$), as was the total ecal fatty acid excretion (3.1 ± 0.71 and 1.14 0.35 g/day, resp., *t* test=11.4, $p<0.001$). The ecal microflora, including the nuclear dehy-rogenating clostridia, were unaltered by the ietary changes as was fecal β-glucuronidase activi-. Dietary changes that increase animal fat intake learly influence fecal bile acid excretion in a ay that would favor the development of large bowel ncer if current theories prove to be true. Di-ary fat, however, has no effect on overall colonic function so other components of the diet must be responsible for the observed associations of bowel cancer with slow transit and reduced fecal bulk.

6019 THE EFFECT OF FAT ON SECRETIN RELEASE.

(Eng.) Miller, T. A.; Konturek, S. J.; Llanos, O. L.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Ann. Surg.* 187(3):303-308; 1978.

To investigate the effect of fat on secretin release, the effect of graded doses of i.v. infused secretin and intestinally perfused sodium oleate and HCl on pancreatic exocrine secretion and plasma secretin was determined in cats and dogs prepared with pancreatic fistulas. The pancreatic dose-response curves for bicarbonate following duodenal perfusion of oleate and HCl in cats were almost identical and paralleled the response to exogenous secretin. Significant elevation of plasma secretin from a basal of 189 ± 41 to 377 ± 80 pg/ml was measured with the administration of 0.5 U/kg/hr of exogenous secretin. The intraduodenal infusion of 0.5 mEq/hr of HCl resulted in a significant elevation of plasma secretin levels from a basal of 257 ± 26 to 400 ± 70 pg/ml. Although the bicarbonate response to oleate in dogs was less pronounced than the response to HCl or secretin (about 50% of that in response to HCl), the bicarbonate output was observed to increase relative to protein output with increasing doses of the intestinally perfused fat. These observations suggest that secretin or a substance with secretin-like activity may be released from the intestine on contact with fat. The inability to detect changes in secretin immunoreactivity in both cats and dogs with increasing doses of oleate suggests that if secretin is released, it is in amounts undetectable by the radioimmunoassay or that some other unknown substance with secretin-like activity may be released.

6020 EFFECT OF LACTULOSE ON AMMONIA PRODUCTION IN A FECAL INCUBATION SYSTEM.

(Eng.) Vince, A.; Killingley, M.; Wrong, O. M. (Univ. Coll. Hosp. Medical Sch., London WC1E 6JJ, England). *Gastroenterology* 74(3):544-549; 1978.

The influence of lactulose on colonic ammonia metabolism was investigated using an *in vitro* fecal incubation system. Lactulose and other fermentable substrates (glucose, mannitol, and sorbitol), pH, and organic acid were varied independently so that their different effects could be determined. Fermentable substrate caused a decrease in ammonia concentration during the period of fermentation ($p<0.01$ with 0.03 M lactulose). Acidification to pH 5.0 or less, with hydrochloric acid or a lactic-acetic acid mixture, significantly reduced ammonia generation ($p<0.001$), but unlike fermentable substrates, did not lower the existing ammonia concentration. The lactic-acetic acid mixture did not reduce ammonia generation significantly below that found with acidification by hydrochloric acid. The effect of lactulose in reducing ammonia concentration is attributed to its role as a bacterial substrate in either increasing bacterial assimilation of ammonia or reducing deamination of nitrogenous compounds. The effect of low pH in reducing generation of ammonia appears to be part of a general reduction in bacterial metabolism.

GENERAL

6040 PRIMATE MESENTERIC BLOOD FLOW: EFFECTS OF VASOPRESSIN AND ITS ROUTE OF DELIVERY. (Eng.) Freedman, A. R.; Kerr, J. C.; Swan, K. G.; Hobson, R. W., II. (Coll. Medicine and Dentistry, of New Jersey--New Jersey Medical Sch., 100 Bergen St., Newark, NJ 07103). *Gastroenterology* 74(5, Part 1):875-878; 1978.

To investigate whether vasopressin is largely inactivated by a single passage through the liver (in which case its effects on the mesenteric circulation should be far greater after intra-arterial than after i.v. administration) or whether it is eliminated primarily via renal glomerular filtration (in which case the route of administration should not influence the drug's effect on regional circulations), the effects of vasopressin on blood flow in the superior mesenteric artery and on mean arterial pressure and portal venous pressure were measured in seven rhesus monkeys. Vasopressin (5×10^{-5} to 5×10^{-2} U/kg) was injected, as either a bolus, or infused both i.v. and intra-arterially to assess the influence of the route of administration upon hemodynamic responses. Dose-dependent decreases in superior mesenteric arterial flow were observed during both intra-arterial and i.v. injections of vasopressin. No statistically significant differences between the two routes of administration, the decreases in flow, and changes in pressure were observed. These observations suggest that i.v. administered vasopressin will be as effective as intra-arterially administered vasopressin in reducing mesenteric blood flow, and thus portal venous pressure, in man. Hence, there is little evidence to favor the intra-arterial use of vasopressin clinically.

6041 THE EFFECTS OF CHOLERA TOXIN ON INTRAMURAL BLOOD FLOW DISTRIBUTION AND CAPILLARY HYDRAULIC CONDUCTIVITY IN THE CAT SMALL INTESTINE. (Eng.) Cedgard, S.; Hallback, D. A.; Jodal, M.; Lundgren, O.; Redfors, S. (Dept. Physiology, Univ. Goteborg, Sweden). *Acta Physiol. Scand.* 102(2):148-158; 1978.

To investigate the possible involvement of circulatory parameters in the pathogenesis of the fluid losses in cholera, blood flow distribution to the mucosa-submucosa and to the muscularis in the cat small intestine was investigated with a ^{85}Kr-elimination technique before and after exposing the intestinal mucosa for 30 min to cholera enterotoxin (50-200 mg/10 cm of intestine). In all experiments, the toxin induced an intestinal secretion. Concomitantly, total intestinal blood flow was increased to a level 50% above control 3 hr after exposure. This vasodilatation reflected a doubling of mean blood flow in the mucosa-submucosa, while muscularis blood flow remained unchanged. In another series of experiments, the effect of cholera toxin on intestinal capillary hydraulic conductivity was investigated by determining the capillary filtration coefficient (CFC). A slight increase in CFC was noted during the 3-hr observation period, but this was not more pronounced than would have been expected from the concomitant vasodilatation. It is concluded that hemodynamic changes in the intestinal mucosa may be one of the several factors that probably are involved in the pathogenesis of cholera.

6042 ELECTROSURGICAL TREATMENT OF EXPERIMENTAL BLEEDING CANINE GASTRIC ULCERS: DEVELOPMENT OF A COMPUTER CONTROL AND A BETTER ELECTRODE. (Eng.) Piercey, J. R. A.; Auth, D. C.; Silverstein, F. E.; Willard, H. R.; Dennis, M. B.; Ellefson, D. M.; *et al.* (Dept. Medicine, Univ. Washington, Seattle, WA 98195). *Gastroenterology* 74(3):527-534; 1978.

An analogue computer that can be inserted in the circuit between a commercial electrosurgical generator and the active electrode is described for the electrosurgical treatment of gastrointestinal bleeding. The efficacy and safety of this technique was tested in experimental bleeding gastric ulcers in dogs. The computer can record the actual energy delivered to the tissue at any arbitrary generator setting. Additionally, it can deliver a predetermined amount of energy by continuously adjusting the voltage of the generator to compensate for changes in the tissue impedance during electrocoagulation (power leveling). A special electrode was devised to assure the reproducibility of the area of tissue contact. By using a force gauge at laparotomy with a predetermined energy of 20 joules, the effect of electrode pressure on the depth of injury was measured. Light pressure (1.3 newtons/cm^2) injured a mean of 36% and moderate pressure (6.4 newtons/cm^2) a mean of 87% of gastric wall thickness. Electrocoagulation applied in the clinical manner, or predetermined by power leveling, stopped all bleeding from experimental gastric ulcers with the same amount of energy for each method. Similarly, chronic studies of the depth of injury with each method of electrocoagulation showed no difference. Furthermore, the whole thickness of the gastric wall was injured in 4% of ulcers treated, and there was no significant difference between the two methods of applying the electrocoagulation. Thus, despite the ability to control energy delivered during monopolar electrocoagulation of experimental gastric ulcers, the depth of injury to the gastric wall is unpredictable and, at times, excessive. Further studies of other types of electrocoagulation are needed and will be facilitated by the availability of this computer-controlled electrosurgical generator.

6043 METABOLIC RESPONSES TO ENTERAL AND PARENTERAL NUTRITION.

(Eng.) Lickley, H. L. A.; Track, N. S.; Vranic, M.; Bury, K. D. (Women's Coll. Hosp., 76 Grenville St., Toronto, Ontario M5S 1B2, Canada). *Am. J. Surg.* 135(2):172-176; 1978.

The metabolism of enteral and parenteral diets were compared to gain information on differences in hormone release with the two routes of administration. Seven pairs of Wistar rats were simultaneously infused with a chemically formulated nutritionally complete amino acid-glucose diet that was delivered, at the same rate, into a central vein or into a feeding gastrostomy. The intragastrically infused rats showed greater weight gain than did the i.v. infused rats ($p<0.05$). This could not be explained by fluid retention, since intake and output were similar in the two groups of animals. There was a greater increase in serum immunoreactive insulin (IRI) at day 8 in the intragastrically infused animals, but a smaller increment in serum immunoreactive pancreatic glucagon (IRG) at that point. Levels of enteroglucagon or glucagon-like immunoreactivity (GLI) were maintained in the intragastrically infused rats but declined markedly in the i.v. infused rats ($p<0.02$) in comparison with that in the intragastrically infused rats after day 8. It is possible that the greater release of IRI seen with the intragastric amino acid-glucose feeding contributes to better disposal of nutrients and greater weight gain. The presence of nutrients in the intestinal lumen may have stimulated the release of GLI, which in turn is insulinotropic.

6044 IMMUNOLOGICAL STUDIES IN ULCERATIVE COLITIS: EXTRACTION, FRACTIONATION, AND IMMUNOLOGICAL CHARACTERIZATION OF GERM-FREE RAT COLON ANTIGEN.

(Eng.) Carlsson, H. E.; Sundblad, G.; Hammarstrom, S.; Perlmann, P.; Gustafsson, B. E. (Dept. Immunology, Univ. Stockholm, S-106 91 Stockholm, Sweden). *Arch. Biochem. Biophys.* 187(2): 366-375; 1978.

Studies were carried out to purify and define the antigen(s) against which patients with ulcerative colitis have antibodies. Intestinal mucins from germ-free rats contained antigens reactive with sera from patients with ulcerative colitis, in addition to human blood group A- and H-like antigens. A crude antigen extract was obtained by phenol-water extraction at 65 C. Two intestinal glycoproteins were purified from the extract by fractionated ethanol precipitation, ion-exchange chromatography, and gel filtration. The glycoproteins (2aI and 4aIIb) were homogeneous in regard to electrical charge and molecular size. Both were glycoproteins of the blood group-substance type. Component 2aI was very rich in *N*-acetylgalactosamine and threonine and low in *N*-acetylglucosamine and sialic acid(s). It had strong blood group A-like activity, weak blood group H activity, and no colon antigen activity as defined by patients' sera. Component 4aIIb was rich in sialic acid(s). About 40% of the sera from patients with ulcerative colitis reacted with this component. No blood group A- or H-like activity could be demonstrated. Colon antigen activity was sensitive to periodate oxidation (0.02 M $NaIO_4$, pH 4.0, 4 C, 18 hr) but resistant to boiling at neutral pH. It was very sensitive to acid hydrolysis (0.01 M HCl, 100 C). In fact, colon antigen activity was significantly reduced when subjected to weak acid hydrolysis under conditions that only appeared to release sialic acids. Further studies are needed to resolve the complex antibody reactivity pattern of sera from patients with ulcerative colitis to colon antigen.

6045 USE OF ARGON LASER IN THE TREATMENT OF EXPERIMENTALLY INDUCED UPPER GASTROINTESTINAL BLEEDING IN PRIMATES.

(Eng.) Butler, M. L.; Morris, W. (Letterman Army Medical Center, Presidio of San Francisco, CA 94129). *Gastrointest. Endosc.* 24(3):117-118; 1978.

The feasibility of using laser photocoagulation in the treatment of upper gastrointestinal bleeding was studied in rhesus monkeys with experimental gastric and duodenal bleeding. Lesions were made using a modified biopsy forceps. Stomach lesions treated by laser irradiation stopped bleeding in an average time of 122 sec, using an average photocoagulation time of 38.8 sec. Lesions left untreated in the stomach bled for an average of 276 sec. In only one animal, bleeding continued after 15 min despite laser therapy. In the duodenum, laser photocoagulated lesions required an average of 110 sec to stop bleeding, while control lesions averaged 190 sec. The average coagulation time with the laser was 28.5 sec. While laser coagulation of mucosal hemorrhage has been found feasible in this primate model, the authors caution that further experimentation is needed before the method is clinically applied in man.

5046 INVESTIGATION OF THE RESORPTION AND RETENTION OF RADIOACTIVE SULFUR IN ALBINO RATS FOLLOWING THE ADMINISTRATION OF ^{35}S-LABELED 3, 5-DIBENZYL-2-THIONO-1,3,5-TETRAHYDROTHIADIAZINE D 47), A SYNTHETIC MUSTARD OIL. DIAGNOSTIC PROCEDURES

6056 HIGH DENSITY, LOW VISCOSITY BARIUM FOR FINE MUCOSAL DETAIL ON DOUBLE-CONTRAST UPPER GASTROINTESTINAL EXAMINATIONS.

(Eng.) Gelfand, D. W. (Bowman Gray Sch. Medicine, Winston-Salem, NC 27103). *Am. J. Roentgenol.* 130(5):831-833; 1978.

A high density, low viscosity barium suspension was developed to maximize demonstration of very small mucosal details on double-contrast upper gastrointestinal examinations. The barium sulfate suspension was formulated using a considerable proportion of large particles (up to 20 μm), thus increasing the potential packing density and decreasing viscosity by decreasing the relative amount of water adsorbed onto the surface of the particles. A low molecular weight dispersant (sodium citrate) was included. Dimethylpolysiloxane was added as an antifoaming agent and sorbitol as a stabilizer. The suspension is capable of 250% weight/volume densities without mechanical mixing, while retaining a low viscosity. *In vitro* tests showed the material to be superior to suspensions of greater viscosity and/or more moderate density in demonstrating fine surface detail. Clinical experience with more than 3,000 examinations with the 250% weight/volume barium suspension has shown the material to be capable of demonstrating areae gastricae or similar fine nodular patterns in approximately 70% of studies. Although a particular preparation has been described, the underlying principles are thought to be generally applicable.

6057 STIGMATA OF RECENT HAEMORRHAGE IN DIAGNOSIS AND PROGNOSIS OF UPPER GASTROINTESTINAL BLEEDING.

(Eng.) Foster, D. N.; Miloszewski, K. J. A.; Losowsky, M. S. (Birch Hill Hosp., Rochdale, Lancastershire, England). *Br. Med. J.* 1(6121):1173-1177; 1978.

To determine satisfactory criteria for identifying patients at high risk of rebleeding after an initial upper gastrointestinal hemorrhage, 245/277 consecutive episodes of suspected upper gastrointestinal bleeding were examined endoscopically. The usefulness of emergency endoscopy in these cases was also assessed. Lesions bearing stigmata of recent hemorrhage were found in 110 of 233 patients who were judged to have bled; 78 had lesions without stigmata and in 45 no lesion was seen. Results in 176 entirely unselected admissions for upper gastrointestinal bleeding were similar: of 153 who underwent endoscopy, 77 had lesions with stigmata, 46 had lesions without stigmata, and 30 had no lesion. Forty-eight chronic duodenal and 41 chronic gastric ulcers were identified by endoscopy. Stigmata were found in 27 and 33 of these cases, resp. Sixteen patients had multiple lesions, and in 12, the presence of stigmata permitted diagnosis of the source of the hemorrhage. Stigmata were more likely to be seen in cases of duodenal ulcer ($p<0.006$), Mallory-Weiss lesions ($p<0.086$), and esophageal varices ($p<0.057$) when endoscopy was performed within 12 hr of bleeding, but were equally common in cases of gastric ulcer after both short and long intervals. In the absence of stigmata, 21 patients with duodenal ulcer had further hemorrhage, and 1 other needed emergency surgery; no patient with gastric ulcer had further hemorrhage or needed emergency surgery. In contrast, when stigmata were present 15/27 patients with duodenal ulcer had further hemorrhage and 17/27 needed emergency surgery; of the 33 patients with gastric ulcer, 10 had further hemorrhag and 15 required emergency surgery. Superficial mucosal lesions may have been the source of hemorrhage when an ulcer unmarked by stigmata was seen a endoscopy. Stigmata were superior to any other single factor or combination of factors in predicting rebleeding and the need for emergency surgery.

6058 BENIGN RETROPERITONEAL EMPHYSEMA ASSOCIATED WITH UPPER GASTROINTESTINAL ENDOSCOPY.

(Eng.) Martin, W. C.; Nagai, N.; Diner, W.; Texter, C., Jr. (Univ. Arkansas for Medical Sciences, 4301 W. Markham St., Little Rock, AR 72201). *Arch. Intern. Med.* 138(5):759-761; 1978.

Two cases of retroperitoneal emphysema and one cas of coexistent retroperitoneal emphysema and pneumoperitoneum that developed after upper gastrointestinal (GI) endoscopy are presented. An 80-yr-old woman developed pneumoperitoneum and retroperitone emphysema following a GI series. Barium leakage did not occur, and she recovered uneventfully. A 75-yr-old woman underwent endoscopy for evaluation of epigastric pain; 5 days later, an i. pyelogram revealed a bubbly lucency around both kidneys, gas at the top of the right kidney, and psoas shadows outlined by gas. Pancreatic body cancer and widespread intra-abdominal metastasis were found at laparotomy. In the third case, a 55 yr-old man developed asymptomatic retroperitoneal emphysema one day after gastroduodenoscopy; bubbly lucencies surrounded the right kidney and psoas shadow and extended up to the right hemidiaphragm. The last two cases also resolved spontaneously. It must be expected that, because of the increased frequency of endoscopic and associated procedures, retroperitoneal emphysema may become more common.

6059 RADIONUCLIDE IMAGING OF BOWEL INFARCTION COMPLICATING SMALL BOWEL INTUSSUSCEPTION IN DOGS.

(Eng.) Kressel, H. Y.; Moss, A. A.; Mon gomery, C. K.; Brito, A. C.; Hoffer, P. B. (Hosp. Univ. Pennsylvania, Philadelphia, PA 19104). *Invest. Radiol.* 13(2):127-131; 1978.

Technetium-99m (^{99m}Tc)-pyrophosphate was investigated for use as an indicator of intestinal infarction in intussuscepted bowel. ^{99m}Tc-pyrophosphate was injected i.v. 24 and 48 hr following the creation of irreducible intussusceptions in eight adult dogs. In six dogs, infarction develop in the intussusception, and each demonstrated increased uptake of ^{99m}Tc-pyrophosphate on *in vivo* scintiscans. The two dogs without infarction show no increased uptake of the radionuclide. Well-counting and specimen scanning confirmed increased radionuclide in the infarcted intussusceptions. These observations suggest that ^{99m}Tc-pyrophosphat is a reliable indicator of the vascular compromise that sometimes occurs with intestinal intussusception.

)60 THE ENZYME LINKED IMMUNOSORBENT ASSAY IN THE DIAGNOSIS OF HUMAN BILHARZIASIS [sic].

:ng.) Farag, H. F.; Barakat, R. M. R. (Medical Res.
ıst., 165 El Horreya Ave., El Hadara, Alexandria,
;ypt). *Tropenmed. Parasitol.* 29(1):12-14; 1978.

ıe sera of 72 patients with *Schistosoma mansoni*
ıd/or *S. hematobium* ova in their stools or urine,
) persons without ova but from schistosomiasis-
ıdemic areas, and 9 healthy persons from areas
.thout schistosomiasis were examined by enzyme-
ined immunosorbent assay (ELISA) to evaluate the
;e of ELISA in the diagnosis of human bilharziosis.
:tinction was measured spectrophotometrically at
)0 nm. The extinction values were 0.088 ± 0.0193,
266 ± 0.1177, 0.547 ± 0.2426, and 0.559 ± 0.2189
›r the 9 controls, 6 patients with *S. hematobium*,
} with *S. mansoni*, and 33 with both parasites, resp.;
ıe values for all patients were significantly dif-
:rent (p<0.0005) from the controls. Among the 16
:sults. No false-negative cases were recorded.
ıe false-positive results may have been due
› cross reactions, a history of schisto-
omiasis, or a low worm burden that escaped clinical
:tection (as in an early stage of infection, as
il the false-positive subjects were 10-15 yr old).
.ISA is a very sensitive and accurate test for the
iagnosis of human bilharziosis.

)61 DIAGNOSIS OF EXOCRINE PANCREATIC INSUFFICIENCY IN CYSTIC FIBROSIS BY THE SYNTHETIC :PTIDE N-BENZOYL-L-TYROSYL-p-AMINOBENZOIC ACID.

:ng.) Nousia-Arvanitakis, S.; Arvanitakis, C.;
:eenberger, N. J. (Kansas Univ. Medical Center,
ıinbow Blvd. at 39th St., Kansas City, KS 66103).
Pediatr. 92(5):734-737; 1978.

ıe urinary excretion of para-aminobenzoic acid
'ABA) following the administration of *N*-benzoyl-L-
'rosyl-PABA was evaluated in 24 patients with cys-
.c fibrosis (CF) and 14 controls as an index of
:ocrine pancreatic function to determine its role
ı the diagnosis of exocrine pancreatic insuffi-
iency. Cumulative percent PABA recovery in 6 hr
ıs significantly lower in CF patients compared with
ıe control group (mean 37% versus 70%, p<0.001).
) overlap was noted between the two groups. There
ıs good correlation between PABA recovery (p<0.001),
:cal chymotrypsin activity (r=0.64, p<0.01), and
›efficient of fat absorption (r=0.66, p<0.01).
ıese findings indicate that PABA recovery is sig-
.ficantly reduced in patients with CF and steator-
ıea and may prove a practical and reliable test of
ıncreatic insufficiency.

)62 ALPHA$_1$-FETOPROTEIN IN THE DIAGNOSIS OF HEPATOMA: STATISTICAL AND COST BENEFIT SPECTS.

(Eng.) Phillips, P. J.; Rowland, R.;
:id, D. P.; Coles, M. E. (Inst. Medical and Veter-
ıary Science, Frome Rd., Adelaide, South Australia
)00, Australia). *J. Clin. Pathol.* 30(12):1129-1133;
)77.

:udies were carried out to determine a diagnostic
lpha$_1$-fetoprotein (AFP) concentration in the sera
f hepatoma patients. Data on the sensitivity and specificity of different diagnostic AFP concentrations were taken from the literature and evaluated statistically and by Bayesian analysis. In 610 patients (hepatoma prevalence 0.028), it was calculated that a sensitive diagnostic concentration (30-50 ng/ml) will misdiagnose hepatoma so often that a positive test will indicate hepatoma in only 10% of cases. A positive test at a specific diagnostic concentration (500 ng/ml) indicates hepatoma in 100% of cases and is preferable in terms of cost benefit. Although the lower concentration will diagnose a larger proportion of patients with hepatoma (74% compared with 59%) the "costs" of excluding false positives are considerable (Australian $2,545 per extra case with 2.5% of patients suffering significant morbidity). In western societies, where the prevalence of hepatoma is low, a higher, less sensitive but more specific diagnostic serum AFP concentration is appropriate for use.

6063 THE DIAGNOSTIC VALUE OF LP-X DETERMINATIONS IN PATIENTS WITH LIVER DISEASE.

(Eng.) Ward, A. M. (Hallamshire Hosp., Sheffield, England). *Protides Biol. Fluids Proc. Colloq.* 25: 333-336; 1977.

The value of lipoprotein X (LP-X) determinations as an additional assessment of cholestasis was examined by analyzing serum samples from a series of 456 consecutive patients with jaundice or other clinical evidence of liver disease. The patients were divided into four major groups (prehepatic disease, 105 patients; hepatocellular disease, 138; extrahepatic biliary and pancreatic disease, 60; malignant disease, 88) and the results of the LP-X assay were compared with the histological and biochemical profiles of each patient to examine the degree of correlation. In the group with prehepatic disease, the two patients with jaundice (postoperative) by histological and biochemical criteria were also LP-X positive. In the group with hepatocellular disease, histology and biochemistry detected 51 cases of essentially intrahepatic cholestasis, but only 32/51 were LP-X positive, and 1 case was LP-X-positive but negative by histology and biochemistry. There was excellent correlation between LP-X and histology/biochemistry determinations in the group with extrahepatic biliary and pancreatic disease (59/74, plus 1 LP-X-positive but histology/biochemistry-negative) with two major exceptions: (1) in cholelithiasis and biliary colic, the LP-X level returned to normal faster than did the enzyme data following passage of the stone, so that six patients with biochemical evidence of cholestasis were LP-X-negative and (2) LP-X determination was unreliable in drug-induced cholestasis (4/6 due to estrogen and 2/8 due to chlorpromazine were LP-X-negative). LP-X determination and the histology/biochemistry profile were in good agreement in cases of malignant disease (17/21, plus 1 LP-X-positive but histology/biochemistry-negative case). LP-X levels were not related to levels of cholesterol, adenosine deaminase, γ-glutamyl transpeptidase, or alanine amino transferase. There was a positive correlation between the levels of LP-X and of bilirubin, alkaline phosphatase, and 5'-nucleotidase, and there was a negative correlation between LP-X and aspartate amino transferase levels.

6064 THE VALIDITY OF ^{99m}Tc-PYRIDOXYLIDENEGLUTAMATE (P.G.) CHOLESCINTIGRAPHY AS A DIAGNOSTIC TEST FOR CHOLECYSTITIS.

(Eng.) Stadalnik, R. C.; Kraus, J. F.; Matolo, N. M.; Krohn, K. A. (Sacramento Medical Center-UCD, 4301 X St.-Unit I, Sacramento, CA 95817). *Clin. Nucl. Med.* 3(4): 142-146; 1978.

The diagnostic value of technetium-99m-pyridoxylideneglutamate cholescintigraphy (^{99m}Tc-PGC) was studied in patients with and without cholecystitis, and its validity was compared with oral cholecystography (OC) and ultrasonography (US). ^{99m}Tc-PGC was applied to 50 patients with acute, subacute, and/or chronic cholecystitis with cystic duct obstruction proven histologically and operatively, and also to 27 healthy volunteers and 43 patients with upper right quadrant abdominal pain who subsequently were proven free of gallbladder disease. In addition, 38 patients had OC and 31 had US performed. The sensitivity and specificity of ^{99m}Tc-PGC were 100%. For OC the sensitivity was 87%, and the specificity was 100%. For US the sensitivity was 70%, and the specificity was 93%. The repeatability of ^{99m}Tc-PGC, OC, and US were 100%, 94% and 81%, resp. These data show that ^{99m}Tc-PGC, a safe and simple technique, is a valid diagnostic tool in the evaluation of patients with cholecystitis.

6065 CHOLECYSTOSONOGRAPHY FOR THE DIAGNOSIS OF CHOLECYSTOLITHIASIS.

(Eng.) Dempsey, P. J.; Phillips, J. F.; Warren, D. L.; Donovan, A. J. (Univ. South Alabama Coll. Medicine, Mobile, AL). *Ann. Surg.* 187(5):465-474; 1978.

Among more than 1,000 cases in which abdominal ultrasound was used because of a suspicion of cholelithiasis with or without obstructive cholecystopathy, the presence or absence of cholelithiasis was established in 86 cases either by surgery or by cholangiographic visualization of the gallbladder. A review of these latter cases is presented. The indications for ultrasound were acute right upper quadrant syndrome (53 cases), cholestasis and hepatic dysfunction (11), confirmation of oral cholangiogram (21), and allergy to iodine-containing dye (1). The gallbladder can be visualized by ultrasound (cholecystosonography) and gallstones seen as echo-producing densities. Under cholecystosonographic observation, the gallbladder can be demonstrated to contract following stimulation by cholecystokinin. This establishes patency of the cystic duct and excludes a diagnosis of acute obstructive cholecystopathy. The gallbladder was visualized in 84/86 patients. Stones were identified sonographically in 64% of 42 patients with proven gallstones (75% of the last 20 cases). The gallbladder contracted following stimulation in 18 of 20 cases with a patent cystic duct. Cholecystosonography is simple, safe, and economical. Cholecystosonography with cholecystokinin stimulation is the first diagnostic study of choice when cholecystolithiasis is suspected and the above-named indications exist. Cholecystosonography may detect gallstones in a gallbladder visualized by oral cholangiography when stones are of the same density as the contrast media.

6066 SONOGRAPHY OF THE COMMON BILE DUCT: VALUE OF THE RIGHT ANTERIOR OBLIQUE VIEW.

(Eng.) Behan, M.; Kazam, E. (Hammersmith Hosp., London W.12, England). *Am. J. Roentgenol.* 130(4): 701-709; 1978.

A method of visualizing the normal or dilated common duct by gray scale ultrasonography is described this method overcomes problems such as difficulty in differentiating between the portal vein and the mildly dilated common hepatic and common bile ducts The patient is scanned longitudinally from the righ anterior abdominal wall with the ultrasound beam directed posteromedially until two tubular structures are demonstrated in the porta hepatis. The more anterior tubular structure in this projection is the common duct. If the common duct is less than 3 mm in diameter, it may not be clearly delineated. In these cases, the absence of common duct dilatation can be inferred. The usefulness of this view for detecting common duct dilatation was evaluated in 101 consecutive cases proven by surgery, autopsy, or cholangiography. The overall accuracy was 96% (4 false-negative studies, no false positives). It is concluded that sonography should be the imaging procedure of choice for suspected extrahepatic biliary obstruction if the serum bilirubin level precludes i.v. cholangiography.

6067 SERUM ISOAMYLASE CHANGES FOLLOWING ENDOSCOPY.

(Eng.) Pelot, D.; Berk, J. E.; Fridhandler, L. (Univ. California Irvine Medical Center, 101 City Drive South, Orange, CA 92668). *Gastrointest. Endosc.* 24(4):166-168; 1978.

Serum amylase changes are reviewed in patients who underwent endoscopic retrograde cholangiopancreatography (ERCP) and upper gastrointestinal endoscopy. Hyperamylasemia occurred in 24 of 36 patients in whom ERCP was performed. The rise was predominantly of pancreatic (P-type) isoamylase in 20 of the 24 with hyperamylasemia and of salivary (S-type) in the remaining 4. In patients in whom the pancreatic duct was visualized, alone or together with the common bile duct, 81.8% displayed hyperamylasemia. Isoamylase analysis revealed that the rise in amylase activity in this particular group was predominantly in P-type isoamylase. By contrast, only 1 of 23 patients with normal pre-examination amylase values who underwent esophagogastroduodenoscopy without attempted cannulation of either the bile or pancreatic duct displayed hyperamylasemia. It is concluded that hyperamylasemia developing after ERCP in which the pancreatic duct had been opacified probably reflect an induced pancreatic alteration.

6068 RADIOANATOMY OF THE SPHINCTER OF ODDI IN MEDICAL CHOLANGIOGRAPHY. (Eng.) Lamarque, J. L.; Bruel, J. M.; Dondelinger, R.; Senac, J. P.; Polge, D.; Rabischong, P.; Bonnel, F. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, June 8-9, 1976.* (Basel: S. Karger): 30-35; 1977.

5096 ORAL CIMETIDINE IN REFLUX ESOPHAGITIS: A
DOUBLE BLIND CONTROLLED TRIAL. (Eng.)
esdorp, E.; Bartelsman, J.; Pape, K.; Dekker, W.;
ytgat, G. N. (Wilhelmina Gasthuis, Amsterdam,
etherlands). *Gastroenterology* 74(5, Part 1):821-
24; 1978.

he efficacy of cimetidine therapy (1.6 g/day) was
valuated in a double-blind placebo-controlled trial
n 24 patients with moderate or severe peptic reflux
sophagitis. Cimetidine was superior to placebo
hen using endoscopic and histological criteria
p<0.01 and p<0.001, resp.). Improved patient
ymptomatology and lower antacid consumption failed
o reach statistical significance. No change in
he abnormally low lower esophageal sphincter pres-
ure was observed at the end of the trial. No
linical side-effects or significant biochemical
hanges were noted. Because of its efficacy, low
oxicity, and low incidence of side-effects, cimeti-
ine appears to be a useful drug in the medical
herapy of reflux esophagitis and could be a valu-
ble alternative to surgery in some cases.

STOMACH

6134 RETAINED GASTRIC ANTRUM SYNDROME DIAGNOSED BY $[^{99m}\mathrm{Tc}]$PERTECHNETATE SCINTIPHOTOGRAPHY. IN MAN: HORMONAL AND RADIOISOTOPIC STUDY OF TWO CASES. (Eng.) Sciarretta, G.; Malaguti, P.; Turba, E.; Fini, A.; Verri, A.; Garagnani, B.; *et al.* (Via Oslavia, 5-40133, Bologna, Italy). *J. Nucl. Med.* 19(4):377-380; 1978.

To improve the differential diagnosis between gastrinoma and retained antrum syndrome (a rare condition, occurring in Billroth II (BII) gastrectomized patients, in which an ulcer recurs associated with high levels of circulating gastrin), two cases of retained antrum syndrome were studied both by gastrin tests (secretin, calcium, protein meal, and bombesin tests) and by $[^{99m}\mathrm{Tc}]$pertechnetate scintiphotography. By the latter method, a prominent area of activity was observed on the anatomic site of the duodenal stump bottom. It appeared after 20 or 30 min and lasted for the 2 hr of observation. After surgical resection, no area of activity was observed at the scintiphotographic follow-up. No false-positive was observed in the more than 30 subjects studied. Scintiphotography by pertechnetate seems able to demonstrate the presence and the size of retained gastric antrum in BII gastrectomized patients with recurrent ulcer.

6135 PROGRESS IN THE CYTOLOGICAL DIAGNOSIS OF GASTRIC LYMPHOMA. (Eng.) Cabre-Fiol, V.; Vilardell, F. (Hospital Santa Cruz y San Pablo, Barcelona 13, Spain). *Cancer* 41(4):1456-1461; 1978.

Experience with 32 cases of gastric lymphoma examined cytologically is reviewed to compare two techniques of diagnosis. In one series (1953-1972), a technique combining washings and abrasion under fluoroscopic control was used. A positive diagnosis of malignancy was made in 7 of 17 cases. In a recent series (1972-1976), 15 cases of gastric lymphoma were studied by direct abrasion during endoscopy. Malignant cells were identified in 13 cases and a correct diagnosis of lymphoma was made in 11 cases. Biopsy was positive for malignancy in 12 cases and lymphoma was specifically diagnosed in 9 instances. Combining cytology and biopsy, a diagnosis of cancer was made in 14 of 15 cases. Endoscopic cytology appears to be far superior to blind abrasion and washings techniques in the diagnosis of lymphoma of the stomach.

6136 IMMUNOLOGICAL STUDIES IN CHRONIC ATROPHIC GASTRITIS AND CHRONIC (SUPERFICIAL) GASTRITIS. (Eng.) Fung, W. P.; Rigby, R. J.; Trenchev, P.; Matz, L. R. (Royal Perth Hosp., Box X2213 GPO, Perth, Western Australia 6001, Australia). *Am. J. Gastroenterol.* 69(1):51-56; 1978.

Detection of autoantibodies, histocompatibility locus antigen (HLA) typing, and immunofluorescence studies on gastric biopsies were carried out in 19 subjects with histologically proven chronic atrophic gastritis (CAG) or chronic superficial gastritis (CG), to clarify the immunological status of gastritis. All patients were seronegative for parietal cell antibody and did not have pernicious anemia. Except for positive antismooth muscle and antimitochrondial antibodies in one patient with CAG, autoantibodies (antinuclear, smooth muscle, mitochrondrial, parietal cell) were absent in patients with CAG and CG. Immunofluorescence studies showed that IgG and IgA were present in the lamina propria of all patients with CAG or CG and of subjects with normal gastric histology. IgM was seen less often, in about half the cases. Complement component C3 was an uncommon finding, being positive only in one case with CAG and one case with CG and in none of the cases with normal gastric histology. Fibrinogen was more commonly seen in patients with CG (5/5 cases) than in those with CAG (3/11 cases). Fibrinogen was found in one patient with normal gastric histology. The most consistent fluorescence was obtained with antiparietal cell antiserum. All subjects with CAG showed negative or weak staining only. In contrast, subjects with CG and normal gastric histology had strong specific fluorescence. An increased frequency of HLA-A1 plus HLA-B8 was found in subjects with CAG (20.7% in controls, 40%

in CAG). The staining pattern in cases of CAG and CG does not suggest immune complex-mediated disease. The presence of fibrinogen and occasionally of C3 supports the idea that the staining is secondary to inflammation.

6137 DIFFUSE VARIOLIFORM GASTRITIS. (Eng.) Lambert, R.; Andre, C.; Moulinier, B.; Bugnon, B. (Hopital E.-Herriot, F-69374 Lyon Cedex 2, France). *Digestion* 17(2):159-167; 1978.

A description of diffuse varioliform gastritis (DVG), a subacute gastric disease characterized by large folds in the fundus and erosive mucosal bulgings disseminated in the fundus and antrum, is presented based on 90 cases of DVG documented during 8 yr (0.3% of examinations). Samples of the fundic and antral mucosae were taken in each patient, along with a fiber endoscopic exploration of the stomach. Epigastric pain simulating peptic ulcer was observed in 63 patients, whereas other patients experienced chronic dull cramps. Twenty-eight patients experienced dyspepsia with anorexia and nausea, 47 patients showed weight loss, and 2 patients had gastrointestinal bleeding. In 67 of the 75 patients who underwent gastric radiological examination, an abnormal pattern was detected showing thick longitudinal folds present in the stomach but not in the antrum, as well as erosive polypoid lesions. Endoscopy showed large folds in the stomach in all patients and extension of the antrum in 74. Microscopic examination showed an increased length of gastric pits, a marked increase of IgE cells, and an eightfold increase in immunocytes per mucosal tissue unit in the fundus and the antrum. Symptoms often appeared suddenly and persisted 1-3 months with quiescent periods of 3 months to 3 yr. The evolution of DVG was followed in 52 patients for 1-5 yr: 15 healed, 28 improved, 8 were unchanged, and 1 worsened. Therapy involving sodium cromoglycate (80-160 mg/day before meals for one month) relieved the symptoms in the seven patients tested; H_2 receptor antagonists (1 g/day) were also found to be effective in the five patients tested.

6138 PROLONGED TREATMENT OF MENETRIER'S DISEASE WITH AN ORAL ANTICHOLINERGIC DRUG. (Eng.) Smith, R. L.; Powell, D. W. (Univ. North Carolina Sch. Medicine, Chapel Hill, NC 27514). *Gastroenterology* 74(5, Part 1):903-906; 1978.

Long-term, high-dose, p.o. anticholinergic drug therapy with propantheline bromide (15 mg/every meal and 30 mg at bedtime, increased over 1 month to 105 mg on a divided-dose schedule maintained for 9 months) was evaluated to determine its effect on gastric plasma protein shedding in a patient with Menetrier's disease. Serial measurements of serum protein components were performed before, during, and after long-term treatment with propantheline bromide. Total serum protein concentration increased significantly ($p<0.02$) during the treatment period from 4.3 ± 0.25 to 5.9 ± 0.55 g/dl during treatment, while albumin increased from a pretreatment value of 2.5 ± 0.12 to 3.4 ± 0.16 g/dl ($p<0.005$). The peripheral edema resolved after 2 months of therapy. The only side-effects were dryness of the mouth and mild urinary symptoms. The improvement in serum protein levels and in symptoms (epigastric tenderness and gnawing epigastric discomfort) continued after therapy was stopped; the serum protein and albumin levels have remained at treatment levels for 6 months. Intensive anticholinergic drug therapy should be tried in this disease before resorting to gastrectomy.

6139 "FOLATE-LOSING GASTROPATHY" AND INTESTINAL FOLATE ABSORPTION IN PATIENTS WITH MENETRIER'S DISEASE (GIANT HYPERTROPHIC GASTRITIS). (Eng.) Belaiche, J.; Matuchansky, C.; Zittoun, J.; Rambaud, J. C.; Bernier, J. J.; Cattan, D. (Hopital de Villeneuve-Saint-Georges, Creteil, France). *Am. J. Dig. Dis.* 23(2):143-147; 1978.

The finding of a decreased serum folate concentration in four patients with Menetrier's disease (MD) led to an investigation of folic acid loss into the gastric lumen concurrently with the intestinal absorption of folate. In each case, there was an increased gastric clearance of plasma proteins, as demonstrated by ^{51}Cr-labeled albumin tests. All the patients had a low serum level of folate and a flat curve of serum folate concentrations after an oral load of folic acid. The gastric loss of folate was determined in the patients and in five controls from the folate concentrations (before and after an i.v. injection of folinic acid) in basal and histamine-stimulated gastric secretion. A significant increase in concentrations and outputs of folate in gastric juice was observed in MD patients compared to controls ($p<0.001$), before as well as after gastric stimulation. None of the patients had abnormalities in jejunal morphology or in xylose absorption. This study shows that folic acid should be added to the list of serum components that may be lost in excess into the gastric lumen in MD patients. The responsibility of this "folate-losing gastropathy" in the folate deficiency that may be observed in MD patients has to be discussed in relation to associated abnormalities in small intestinal folate transport.

6140 GASTRIC MUCOSAL PERMEABILITY AND GASTRIC ACID SECRETION BEFORE AND AFTER HEMODIALYSIS IN PATIENTS WITH CHRONIC RENAL FAILURE. (Eng.) Shapira, N.; Skillman, J. J.; Steinman, T. I.; Silen, W. (Harvard Medical Sch., Boston, MA). *Surgery* 83(5):528-535; 1978.

Gastric mucosal permeability and gastric acid secretion were assessed in 16 patients in chronic renal failure before and after maintenance hemodialysis and in 13 normal healthy subjects by the acid-free lithium-polyethylene glycol technique. Half of the uremic patients had increased gastric mucosal permeability (IGMP) before dialysis in comparison with the normal control subjects ($p<0.001$). A significant improvement in gastric mucosal permeability ($\Delta[Li^+/PEG]$) occurred in the IGMP group after dialysis ($p<0.025$). Decreases in systolic ood pressure during hemodialysis were correlated ch increases in gastric mucosal permeability =0.72, $p<0.01$). Gastric acid secretion ($\Delta[H^+/PEG]$) s significantly lower ($p<0.001$) in the uremic ients than in normal subjects, but was increased ward normal levels after dialysis. There was a near correlation between changes in gastric acid cretion and the secretion of pepsin (Δ[pepsin/PEG]) uremic patients before and after hemodialysis =0.77, $p<0.001$). Serum gastrin concentrations re markedly elevated in uremic patients (608 ± and 331 ± 137 pg/ml in patients with normal and creased mucosal permeability, resp.) and were affected by dialysis. It is possible that the nstellation of high serum gastrin levels, abnormal stric mucosal permeability, and restoration of stric acid secretion toward more normal levels ter dialysis in patients with chronic uremia are lated to the increased incidence of gastroduodenal ceration that has been reported to occur in ese patients.

1 ALKALINE GASTROESOPHAGEAL REFLUX. (Eng.)

Pellegrini, C. A.; DeMeester, T. R.; Wern- J. A.; Johnson, L. F.; Skinner, D. B. (Univ. cago Pritzker Sch. Medicine, 950 E. 59th St., cago, IL 60637). *Am. J. Surg.* 135(2):177-184; 8.

determine the significance of alkaline secretions the development of reflux esophagitis, the re- ionship between acid and alkaline reflux was died in patients with symptoms of reflux and con- ls, using 24-hr pH monitoring of the distal esoph- s. The upper level of physiologic reflux was de- mined from the percentage of time and the number episodes during which the pH was <4 or >7 and the n duration of each episode in 15 asymptomatic jects. One hundred patients with symptoms of troesophageal reflux were divided into four groups the basis of 24-hr pH monitoring: those with ab- mal acid but normal alkaline reflux (termed acid luxers, 51 patients), those with both abnormal d and alkaline reflux (termed acid-alkaline re- xers, 25), those with normal acid and abnormal aline reflux (termed alkaline refluxers, 6), and se with both normal acid and alkaline reflux rmed nonrefluxers, 18). Nonrefluxers had a simi- incidence of heartburn, regurgitation, and dys- gia as did acid and acid-alkaline refluxers, ving the inaccuracy of symptoms for detecting lux. Alkaline refluxers had a lesser incidence heartburn but a greater incidence of regurgita- n, and four alkaline reflux patients presented h severe pulmonary disease secondary to aspiration. ilar incidence and degree of esophagitis was seen acid, acid-alkaline, and alkaline refluxers. All ee groups of symptomatic refluxers had a mean tal esophageal sphincter pressure (DESP) sig- icantly lower than that of the controls ($p<0.02$). re was no difference in the DESP between controls symptomatic nonrefluxers. Nine patients with d-alkaline reflux and one patient with alkaline lux underwent an antireflux procedure and were tudied 3 months postoperatively. All 10 patients a 24-hr pH acid score within normal limits, but had an abnormal 24-hr pH alkaline score. In both patients, reflux was demonstrated after placing an acid load in the stomach. It is concluded that symptomatic gastroesophageal reflux in patients with an intact gastrointestinal tract is a mixture of both acid and alkaline secretions, with one or both being abnormal due to different degrees of acid production and pyloric regurgitation. Patients with alkaline reflux may develop serious complications of reflux in the absence of typical symptoms of heartburn. Twenty-four hour pH monitoring of the esophagus is useful in the identification of these patients and in evaluating the ability of an antireflux procedure to control both abnormal acid and alkaline reflux.

6142 SERUM CARBENOXOLONE IN PATIENTS WITH GASTRIC AND DUODENAL ULCER: ABSORPTION, EFFICACY AND SIDE EFFECTS. (Eng.)

Baron, J. H.; Gribble, R. J. N.; Rhodes, C.; Wright, P. A. (Hammersmith Hosp., London W12 OHS, England). *Gut* 19 (4):330-335; 1978.

The absorption of carbenoxolone sodium was studied in 15 patients with gastric ulcer and 8 patients with duodenal ulcer treated for four weeks, and the results were correlated with clinical, endoscopic, and metabolic responses. The gastric ulcer patients were treated with Biogastrone: 9/15 received 100 mg on day 1 and 100 mg 3 times/day on days 2-28 and 6/15 received 100 mg on day 1, 100 mg 3 times/day on days 2-7, and 50 mg 3 times/day on days 8-28. The duodenal ulcer patients were treated with Duogastrone (50 mg on day 1 and 50 mg 4 times/day on days 2-28). Blood levels of carbenoxolone showed a log distribution, varied markedly between patients, and were markedly higher after Biogastrone tablets than after Duogastrone capsules. Serum carbenoxolone levels were similar in patients taking Biogastrone tablets before or after meals, and in patients taking Biogastrone tablets or Duogastrone capsules with or without antacids following chronic administration. Serum carbenoxolone levels were similar in patients whose gastric ulcers had or had not healed after 4 weeks of treatment. Serum carbenoxolone was significantly higher in patients who developed edema ($p<0.04$-0.06) and was significantly correlated with age ($r=0.57$, $p<0.03$) and with fall in plasma potassium ($r=0.69$, $p<0.0005$). Carbenoxolone may exert its metabolic effects systemically but its ulcer-healing effects topically; additional studies are needed to test this hypothesis.

6143 CIMETIDINE AND PLACEBO IN THE TREATMENT OF BENIGN GASTRIC ULCER: A MULTICENTER DOUBLE BLIND STUDY. (Eng.)

Dyck, W. P.; Belsito, A.; Fleshler, B.; Liebermann, T. R.; Dickinson, P. B.; Wood, J. M. (Scott and White Memorial Hosp., Temple, TX). *Gastroenterology* 74(2):410-415; 1978.

A randomized, prospective, multicenter trial of the effects of cimetidine on benign gastric ulcer was conducted in 60 out-patients. Healing was assessed endoscopically. Although none of the differences was statistically significant, mean healing rates were higher and mean decreases in ulcer size were greater with cimetidine than they were with placebo.

Twenty-four percent of the ulcers healed completely in 2 weeks when cimetidine (300 mg 4 times/day) was administered, compared with a placebo healing rate of 14%. At 6 weeks, the incidence of healing increased to 60% in the cimetidine group and 41% in the placebo group. The mean percentage of decrease in ulcer size was greater at both 2 and 6 weeks in the cimetidine group than it was in the placebo group. In both the cimetidine and placebo groups, relatively liberal intake of a potent antacid occurred, despite recommendations that antacid be taken only for ulcer pain and despite a reported low frequency of ulcer pain throughout the study. The role of potent antacids in treatment of gastric ulcers has not been defined definitively. Thus, a possible beneficial effect of cimetidine may have been obscured. For a more clear discrimination between the effects of cimetidine and placebo in the healing of gastric ulcer, studies utilizing either no antacid or antacids of low neutralizing capacity will be needed.

6144 CIMETIDINE, ANTACID, AND HOSPITALIZATION IN THE TREATMENT OF BENIGN GASTRIC ULCER: A MULTICENTER DOUBLE BLIND STUDY. (Eng.) Englert, E., Jr.; Freston, J. W.; Graham, D. Y.; Finkelstein, W.; Kruss, D. M.; Priest, R. J.; *et al.* (Veterans Admin. Hosp., 500 Foothill Drive, Salt Lake City, UT 84148). *Gastroenterology* 74(2, Part 2):416-425; 1978.

A controlled clinical trial was carried out in 206 patients with benign gastric ulcer to assess the effect on healing of cimetidine, antacids, and hospitalization. In-patients and out-patients were randomly assigned to one of three treatments: cimetidine plus antacid, cimetidine plus dummy antacid, or placebo tablet plus antacid. Ulcer healing as shown by endoscopy occurred by 12 days in 11-26% and by 42 days in 58-76% of the patients. There were no significant differences in healing between hospitalized and nonhospitalized patients or between treatment subgroups. Symptomatic response was equivalent in all groups. The median antacid consumption was 328 mEq of *in vitro* buffering capacity daily. Patients taking antacids experienced significant ($p<0.01$) diarrhea compared with those taking no antacid. This investigation suggests that the effect of cimetidine is equivalent to that of large amounts of antacid, but because a true placebo group was not studied, it is not possible to conclude from this study alone whether either agent influenced healing. In contrast to widespread belief, initiation of treatment in the hospital did not enhance healing, but because patients were not randomly assigned to inpatient and outpatient status, no final conclusion about the effect of hospitalization on healing can be drawn.

6145 ROUTINE TOTAL GASTRECTOMY FOR OPERABLE GASTRIC CANCER [Abstract]. (Eng./Ger.) Pichlmayr, R.; van Alste, H. E. (Medizinische Hochschule Hannover, Karl-Wiechert-Allee 9, D-3000 Hannover, W. Germany). *Langenbecks Arch. Chir.* 345:595; 1977.

9 MEASUREMENT OF GASTRIC MUCOSAL BLOOD FLOW IN MAN. (Eng.) Guth, P. H.; Baumann, H.; ssman, M. I.; Aures, D.; Elashoff, J. (691/111C erans Admin. Wadsworth Hosp. Center, Wilshire Sawtelle Blvd., Los Angeles, CA 90073). *Gas-enterology* 74(5, Part 1):831-834; 1978.

determine whether the ^{14}C-aminopyrine (AP) clear-e technique can be used to measure gastric mu-al blood flow in man and, if so, whether the io of blood flow to acid secretion is different duodenal ulcer (DU) patients than in normal sub-ts, the clearance of ^{14}C-AP from plasma into gas-c juice was studied in five normal men and five with duodenal ulcer during the infusion of step-e increasing doses of pentagastrin (25-2,000 ng/ hr). Acid secretion in response to high doses of tagastrin (222, 666, and 2,000 ng/kg/hr) was sig-icantly greater ($p<0.05$) in DU patients than in mal subjects. For each dose of pentagastrin, the -AP clearance rate increased in both normal and subjects, and its mean rate of clearance was al-s greater in DU subjects, though the difference not statistically significant. There was a sig-icant correlation between rate of acid secretion clearance of ^{14}C-AP in both the normal subjects ($r=0.76$) and the DU patients ($r=0.71$), and the slopes and intercepts of the lines relating these two variables did not differ significantly between the two groups. Similarly, R, the ratio of gastric juice to plasma AP concentrations, which is also a measure of the milliliters of blood flow for each milliliter of juice secreted, showed a negative correlation with rate of acid secretion in both DU patients and normal subjects, and the slopes and intercepts of the lines relating R to acid secretion did not differ significantly between the two groups. The relation between acid secretion and clearance of ^{14}C-AP in man is similar to that found in earlier studies in dog, a species in which clearance of AP has been shown to be a valid measure of mucosal blood flow. It is concluded that clearance of ^{14}C-AP from plasma into gastric juice appears to be a valid measure of mucosal blood flow in man and that the relationship between rate of acid secretion and clearance of ^{14}C-AP is similar in normal subjects and in patients with DU.

6200 EFFECT OF BILE ACIDS AND pH ON THE RELEASE OF ENTEROPEPTIDASE IN MAN. (Eng.) Rinderknecht, H.; Nagaraja, M. R.; Adham, N. F. (Veterans Admin. Hosp., Sepulveda, CA 91343). *Am. J. Dig. Dis.* 23(4):332-336; 1978.

Because bile acids increase the release of the human brush border enzymes enteropeptidase (EP), alkaline phosphatase (AP), and leucine aminopeptidase (LAP) from duodenal mucosa and because the action of bile acids is independent of their known enhancing effect on enteropeptidase activity, the effects of glycodeoxycholate and pH on the release of these three enzymes was studied in human duodenal biopsies to clarify the kinetics of the release. Glycodeoxycholate (2.5 mM) enhanced the release of both EP and AP (expressed as percent total enzyme/g wet tissue) at both pH 6.3 and pH 8.2 ($p<0.001$ and $p<0.004$ for EP and AP, resp., at pH 6.3; $p<0.002$ for both EP and AP at pH 8.2). However, both EP and AP were released to a greater extent at pH 8.2 than at pH 6.3 in the absence of bile acid (15.4 ± 2.8% at pH 6.3 versus 36.2 ± 6.3% at pH 8.2, $p<0.005$, for EP; 5.2 ± 0.7% at pH 6.3 versus 14.4 ± 3.4%, $p<0.005$ for AP), the enhancement being comparable to that produced by glycodeoxycholate on either enzyme at either pH. Contrary to some results obtained with animal tissue by other investigators, these experiments with human duodenal mucosa indicate that EP, under all conditions tested, is released at a rate considerably greater than that for AP or LAP. The looser association of EP with cellular components relative to that of other brush border enzymes, as indicated by the observations, may be related to the unique function of EP as the trigger enzyme of protein digestion. The pH of duodenal juice is a hitherto unrecognized factor in the release mechanism of brush border enzymes.

6201 INTESTINAL PHASE OF GASTRIC SECRETION IN PATIENTS WITH DUODENAL ULCER. (Eng.) Konturek, S. J.; Kwiecien, N.; Obtulowicz, W.; Sito, E.; Oleksy, J. (Inst. Physiology, 16 Grzegorzecka St., 31-531 Krakow, Poland). *Gut* 19(4):321-326; 1978.

Studies were carried out to establish the existence of the intestinal phase of gastric secretion in man and to compare it in healthy subjects and duodenal ulcer patients. In 10 healthy subjects and 10 duodenal ulcer patients, the intestinal phase of gastric acid secretion was studied by intraduodenal infusion of a 10% liver extract meal (pH 7) at 400 ml/hr for 3 hr. A gastroduodenal double-lumen tube with two balloons was used to block the pylorus and to prevent duodenogastric reflux. Gastric acid response to a duodenal meal of liver extract reached a peak at the end of the first hour of infusion of the extract and was then followed by a relatively well-sustained plateau. When the figure was normalized as a percentage of peak response to pentagastrin, it was about 45% in healthy subjects and 63% ($p<0.05$) in duodenal ulcer patients. Serum gastrin concentration increased significantly ($p<0.05$) during a duodenal meal of liver extract only in duodenal ulcer patients and not in healthy subjects. The combination of the duodenal meal of liver extract with pentagastrin infusion resulted in a significantly greater ($p<0.05$) increase in acid output i duodenal ulcer patients than in healthy controls. Duodenal perfusion with a liver extract meal in which the pH was gradually decreased caused a pH-dependent reduction in acid output, but not in serum gastrin, both in the duodenal ulcer patient and in healthy subjects. This study shows that th intestinal phase in man results in a potent gastri acid stimulation that is pH-dependent, greatly augmented by pentagastrin, and more vigorous in duodenal ulcer patients than in healthy controls.

6202 GIANT DUODENAL ULCERS. (Eng.) Eisenbe R. L.; Margulis, A. R.; Moss, A. A. (Ve erans Admin. Hosp., 4150 Clement St., San Francis CA 94121). *Gastrointest. Radiol.* 2(4):347-353; 1978.

To improve the diagnosis of and reduce the mortal from giant duodenal ulcers, clinical, radiologica and therapeutic results from 26 patients with gia duodenal ulcers are reviewed. The concept of the ulcer/bulb ratio (ratio of longest diameter of th ulcer to that of the total bulb including the ulc is introduced. In all cases this ratio was 0.8 o greater; in 18 cases, the ulcer completely replac the duodenal bulb. An "ulcer within an ulcer" appearance, representing a small area of deeper ulc ation within the giant ulcer, was noted in 8 case Half of the patients have remained symptom-free o medical therapy alone. Only two patients in the series died of complications of giant duodenal ulcer (one of hypovolemic shock 6 weeks postoperatively, one of massive hemorrhage shortly after admission). Five of the six patients requiring surgical intervention did well after surgery. It is suggested that a course of intensive medical therapy be attempted prior to surgical interventi

6203 PROPHYLACTIC EFFECT OF CIMETIDINE IN DU DENAL ULCER DISEASE. (Eng.) Gudmand-H er, E.; Jensen, K. B.; Krag, E.; Rask-Madsen, J.; Rahbek, I.; Rune, S. J.; *et al.* (Herlev Univ. Hos 2730 Herlev, Denmark). *Br. Med. J.* 1(6120):1095-1097; 1978.

Fifty-seven symptom-free patients with duodenal u entered a double-blind trial to assess the prophylactic effect of cimetidine. Patients were rando allocated to receive cimetidine (400 mg b.i.d., 29 patients) or placebo (28 patients). The trial was designed to imitate daily clinical practice, duodenal ulcer disease was diagnosed by means of x-ray examination. Three patients from each grou withdrew from the trial. All remaining patients continued to receive treatment for 12 months or u til symptoms recurred. Three of 28 patients suffered relapses during cimetidine treatment, compa with 20 of 25 receiving placebo. No side-effects were attributable to cimetidine. Long-term cimet dine treatment had no curative effect as relapses occurred soon after treatment was stopped. The estimated chance (cumulative remission rate ±2 SE of remaining symptom-free for 13 weeks after 1 yr of cimetidine treatment was 47 ± 21%. Maintenanc treatment with cimetidine is a suitable alternati elective surgery in patients with duodenal ulcer ject to frequent relapses. Further study is ded to establish the optimal duration and safety prolonged cimetidine treatment.

4 SECRETION OF INTRINSIC FACTOR AND HYDROCHLORIC ACID AFTER 12 WEEKS' TREATMENT H CIMETIDINE. (Eng.) Epstein, O.; Judelman, J.; an, G.; Ardeman, S. (Royal Free Hosp., London, land). *Gut* 19(4):327-329; 1978.

effect of cimetidine on intrinsic factor and production was studied in patients undergoing atment for 12 weeks. A sample of 16 patients pentagastrin stimulation studies performed bee starting the 12-week course of cimetidine, and in 12 hr after completing the course. Basal pentagastrin-stimulated intrinsic factor setion was assayed in 13 patients. There was no nificant difference in the pattern of secretion er 12 weeks of cimetidine treatment. The al and peak acid outputs of all 16 patients were sured. No significant difference was found in pattern of acid secretion after treatment. It ears that parietal cell secretory function is tored to normal within 12 hr of discontinuing a longed course of cimetidine.

6219 IN VIVO METABOLISM OF PLASMA FREE FATTY ACIDS BY INTESTINAL MUCOSA OF MAN. (Eng.)

Gangl, A.; Renner, F. (II. Universitatsklinik fur Gastroenterologie und Hepatologie, Garnisongasse 13, A-1090 Vienna, Austria). *Gastroenterology* 74(5): 847-850; 1978.

Because the free fatty acid (FFA) supply to the intestinal mucosa has two sources (the gut lumen and the plasma pool) and because the FFA from these sources have different metabolic fates, the metabolism of plasma FFA was studied in the mucosa of the upper jejunum in 12 patients *in vivo*. After rapid i.v. injection of ^{14}C-palmitic acid complexed to human albumin, serial jejunal biopsies were performed with a hydraulic biopsy tube. Specimens of jejunal mucosa were homogenized and assayed for lipids and radioactivity. The mean half-time of initial ^{14}C-FFA disappearance from plasma was 2.0 min. Uptake of ^{14}C-plasma FFA by the mucosa of the entire small bowel was estimated as 0.7%. Of mucosal radioactivity, 25.2% was recovered in water-soluble metabolites, suggesting local oxidation of plasma FFA; 31.7% was incorporated into phospholipids, 16.5% into triglycerides, and 9.7% was esterified with cholesterol. The specific activity of mucosal triglyceride-fatty acids was about 10-fold higher than the specific activity of serum triglyceride-fatty acids during the first 15 min after the i.v. injection of ^{14}C-palmitate, thereby establishing for the first time in man *in situ* esterification of plasma FFA by intestinal mucosa. It is therefore concluded that in man, plasma FFA also serve as a constantly available source of energy and of precursors for more complex lipids in the absorptive intestinal epithelium. It is speculated that, as in rats, part of the ester lipid synthesized *in situ* from plasma FFA may subsequently leave the absorptive cells incorporated in lipoproteins. Quantitatively this pathway must be minute, however, under normal conditions.

6220 PRIMARY MALIGNANT TUMORS OF THE SMALL INTESTINE. A TWENTY-TWO YEAR EXPERIENCE WITH THIRTY PATIENTS. (Eng.)

Sager, G. F. (7 Bramhall St., Portland, ME 04102). *Am. J. Surg.* 135(4):601-603; 1978.

A review of 30 cases of primary malignant small bowel tumors is presented. Chronic obstruction was the presenting symptom most frequently encountered (13 patients), with an acute abdomen from perforation of the tumor next in frequency (6 patients). Adenocarcinoma (14 patients) and carcinoid (12 patients) were the most frequent findings, and more than half of all tumors (16/30) were found in the ileum. Five of 30 patients survived: 3 are alive and well and 2 are alive on chemotherapy. Five of these died of other causes. Of 27 patients explored for symptomatic small bowel cancers, only 1 is alive free of tumor. Malignant small bowel tumors are difficult to diagnose early and have a poor prognosis.

6221 PRIMARY LYMPHOMAS OF THE GASTROINTESTINAL TRACT. I. PLASMA CELL TUMOURS. (Eng.)

Henry, K.; Farrer-Brown, G. (Westminster Medical Sch., London, England). *Histopathology* 1(1):53-76; 1977.

The histology of 125 cases of primary gastrointestinal lymphomas arising in the stomach and small an large intestines is reviewed. The material was gathered from the Bland-Sutton Institute of Pathology at the Middlesex Hospital and from the Westminster Hospital. Of the initial total of 143 cases diagnosed, 18 were rejected. Of the acceptable 125 cases, 51 lymphomas arose in the stomach, 53 in the small intestine, and 21 in the large intestine including the rectum. Excluding the four children in the series, ages ranged from 18 to 82 and were fairly evenly distributed across the decades. There was no significant sex difference in the Middlesex Hospital cases, but in the Westminster Hospital series, the male to female ratio was approximately 2.6 to 1. One significant finding to emerge from this histological survey, and that forms the basis of this communication, is the proportion of lymphomas considered to be predominantly of plasma cell type. These plasma cell tumors, or extramedullary plasmacytomas, accounted for 49 of the 125 cases of gastrointestinal lymphomas. They were less common in the stomach and most common in the intestine, the majority occurring in the ileocecal region. Conversely, Hodgkin's disease, in contrast to some series, was not encountered. Of the non-Hodgkin's lymphomas, grade I tumors were uncommon, and true histiocytic lymphomas were distinctly rare. The high incidence of plasma cell tumors in this series is in keeping with the morphological findings of a previous study carried out in patients with alpha-chain disease and in a small series of primary gastrointestinal lymphomas.

6222 "MEDITERRANEAN ABDOMINAL LYMPHOMA" OR IMMUNOPROLIFERATIVE SMALL INTESTINAL DISEASE. PART II: PATHOLOGICAL ASPECTS. (Eng.)

Nassar, V. H.; Salem, P. A.; Shahid, M. J.; Alami, S. Y.; Balikan, J. B.; Salem, A. A.; *et al.* (Grady Memorial Hosp., 80 Butler St., S.E., Atlanta, GA 30303). *Cancer* 41(4):1340-1354; 1978.

The pathology of 25 cases of Mediterranean abdomin lymphoma, better designated as immunoproliferative small intestinal disease (IPSID), that were seen a the American University of Beirut Hospital is reviewed. The series includes nine cases with documented alpha-heavy chain disease (α-HCD). IPSID i characterized by the presence of a diffuse and compact bandlike lymphoplasmacytic infiltration of th proximal small intestinal mucosa. The presence of a concomitant malignant lymphoma in the intestine and/or mesenteric lymph nodes and of alpha-heavy protein in the serum is commonly encountered. Two histopathologic variants of IPSID are present. Th first is characterized by the diffuse infiltratio of the mucosa, at sites away from tumoral masses, by either pure plasmacytic infiltration or by mixe lymphoplasmacytic infiltration. This variety is associated with the immunoblastic sarcoma type of malignant lymphoma, and with α-HCD. The second variant is characterized by a diffuse follicular lymphoid hyperplasia pattern in the small intestin

mucosa. The associated malignant lymphoma is
ffuse and undifferentiated often having a starry-
y pattern. This variety is not associated with
HCD. Both histologic variants share the same
inical antecedents. In five patients, mesenteric
mph nodes harbored immunoblastic sarcoma while
e intestinal mucosae of the same patients were
volved with a benign-appearing lymphoplasmacytic
filtration. This finding stresses the need for
aging laparotomy. Three patients, with α-HCD,
d peripheral lymph node involvement with immuno-
astic sarcoma. The disease apparently evolves
two stages: an immunoproliferative phase, prob-
ly reversible, and a later development of malig-
nt lymphoma. The term IPSID accurately describes
e nature of the entity.

23 EOSINOPHILIC ILEITIS. (Fre.) Germain, M.;
Lemaigre, G.; Lapierre, J.; Lenriot, J.
entre Hospitalier de Longjumeau, 91160 Longjumeau,
ance). *J. Chir. (Paris)* 114(5):377-384; 1977.

sinophilic ileitis, found almost exclusively in
e coastal areas of Japan, Brittany, and the
therlands, has long been attributed to infesta-
ons with ascarids, *Anisakis* or *Eustoma rotundatum*
rvae (the latter two parasitic larvae are ac-
ired by eating raw fish). A case of possibly
nparasitic eosinophilic ileitis in a 17-yr-old
y is discussed. As in the majority of cases,
mptoms mimicking appendicitis led to a surgical
tervention that revealed two 10-cm segments of
ickened, discolored ileum. A segmental resection
s performed. The patient had a marked eosino-
ilia (11% of WBC). Antibody titers to *Toxocara*
nis were borderline positive, but no parasites
uld be found in the stools or lesions. Recovery
s uneventful. Histologically, the eosinophilic
anulomas are easily identified by the character-
tic eosinophilic infiltration. Clinical diag-
sis is difficult, but the disease may be sus-
cted in patients with a history of allergies,
ving appendicitis-like symptoms and eosinophilia
eater than 10% of WBC. Medical treatment (piper-
ine, delta-cortisone) may be attempted in non-
gent cases. There is often a tendency towards
ontaneous regression of the ileitis. In all
ses the diagnosis can only be confirmed by histo-
gic examination.

24 ALTERATIONS IN INTESTINAL STRUCTURE, FAT
ABSORPTION AND BODY WEIGHT AFTER INTES-
NAL BYPASS FOR MORBID OBESITY. (Eng.) Friedman,
I.; Chandler, J. G.; Peck, C. C.; Nemeth, T. J.;
um, S. K. (Letterman Army Inst. Res., Presidio
n Francisco, San Francisco, CA). *Surg. Gynecol.*
stet. 146(5):757-767; 1978.

document the morphologic alterations in the
all intestine after intestinal bypass, 11 pa-
ents who underwent jejunoileal bypass for morbid
esity were studied. Serial intestinal biopsies
re obtained prior to and at timed intervals fol-
wing operation in both fasted and fat-fed states.
llus height increased asymptotically, reaching
plateau at 80% in excess of the preoperative
value (0.42 ± 0.08 mm) after operation. Fat ingestion did not affect villus height. The postbypass body weight reached a plateau at 63.9 ± 11.1% of initial body weight over a 16-month period and correlated linearly ($r=-0.97$, $p<0.1$) with villus height following an asymptotic curvilinear course. The time required to attain 90% of total body weight loss was 15.9 months. A study of intestinal fat absorption at both the light microscopic and ultrastructural levels showed that the enlarged villi were lined along the entire villus by functionally mature epithelium capable of transporting lipid. The normal pattern of intracellular lipid accumulation remained constant preoperatively and postoperatively. Villus hypertrophy is an important mechanism in the plateauing of weight loss after jejunoileal bypass for morbid obesity.

6225 THE PREVENTION OF BYPASS ENTERITIS AFTER JEJUNOILEAL BYPASS FOR MORBID OBESITY. (Eng.) Hubbard, T. B., Jr. (Mercy Hosp., 301 St. Paul Pl., Baltimore, MD 21202). *Ann. Surg.* 187(5): 502-509; 1978.

A preliminary report of efforts to devise a valve to prevent reflux into the bypassed intestine after jejunoileal bypass is presented. Valve I (42 cases) was formed by dividing the ileum, everting the proximal end as one matures an ileostomy, and inserting this into the distal ileum. Only 12 of these valves were competent. Valve II (6 cases) was formed by dividing the ileum and merely inserting the proximal bowel into the distal, allowing it to evert spontaneously as with an unmatured ileostomy. In two cases, the valve was competent, but four cases became obstructed and this valve is mentioned only to be condemned. Valve III (19 cases) is similar to an isoperistaltic Kock valve, except that the intussuscepted ileum is first divested of its mesentery. All such valves have been competent. All 33 patients with a competent valve have been free of the stigmata of bypass enteritis, whereas 54% of 156 patients showed the symptoms of enteritis after conventional jejunoileal bypass.

6226 GROWTH, HEALTH, AND DEVELOPMENT AFTER NEONATAL GUT SURGERY: A LONG-TERM FOLLOW-UP. (Eng.) Tejani, A.; Dobias, B.; Nangia, B. S.; Mahadevan, R. (Methodist Hosp., 506 Sixth St., Brooklyn, NY 11215). *Pediatrics* 61(5):685-693; 1978.

Growth and development data on 19 children who survived gut surgery in the immediate newborn period were studied to evaluate the quality of life following neonatal gut surgery. The follow-up period ranged from 7 months to 7 yr, 6 months, with a mean of 3 yr, 8 months. Neonates who underwent gut resection were at a higher risk for delay in height and weight gain compared with those who had gut surgery without resection. Six of the 12 children who had gut resection showed delay in height gain, and 7 showed delay in weight gain. Of the seven children who had gut surgery but no resection, only one showed delay in height and weight gain after the age of 1 yr. An individual approach and careful serial follow-ups are recommended for all children undergoing gut resection in the newborn period. Of the eight children who had psychometric testing in the gut-resected group, only two are normal. Three of the four older children in this group show signs of perceptuomotor defects, suggesting the need for subtesting such children at about 6 yr of age so that remedial help, if necessary, may be provided when formal schooling begins.

clinical picture and laboratory findings in 24
ients with celiac disease who were diagnosed
er 4 yr of age are presented. The classical
nical picture was rare; growth retardation and
mia were the most common presenting features,
rt stature being present in 17, and low hemo-
bin levels (<11 g/dl) in 20 patients. The ane-
was mainly hypochromic with low serum iron
0 μg/dl in 16/19 cases), but low serum folic
d (<2.7 ng/ml) was also a consistent finding
/19). Abdominal pain was a feature in 42% of
cases. A history of bowel habit was very un-
iable, and diarrhea was often episodic in nature.
single laboratory test seemed to be an effective
eening test for malabsorption. This fact empha-
es the importance of intestinal biopsy, particu-
ly with children presenting with retarded growth
anemia, with or without gastrointestinal symp-
s.

9 FURTHER EVIDENCE OF A PRIMARY MUCOSAL DE-
FECT IN COELIAC DISEASE. (Eng.) Cornell,
J.; Rolles, D. J. (Royal Melbourne Inst. Tech-
ogy, 124 LaTrobe St., Melbourne, Victoria, 3000,
tralia). *Gut* 19(4):253-259; 1978.

basic chemical structure of fraction 9 components of a peptic-tryptic-pancreatinic digest of wheat gliadin was analyzed for a better understanding of the toxicity of fraction 9 for celiac disease patients. Subfractions of fraction 9 were subjected to *in vitro* mucosal digestion and the filtrates were examined for residual peptides. Small intestinal mucosa from four groups of individuals were studied: eight patients with celiac disease in remission, eight healthy controls (2 adults and 6 children), nine first-degree relatives (2 adults and 7 children) of patients with celiac disease, and six children with recurrent diarrhea investigated for possible celiac disease, but in whom the diagnosis was excluded. The highest amounts of residual peptides (measured by scanning densitometer) were detected after digestion with mucosa from patients with celiac disease and the lowest amounts from the controls ($p<0.001$). The results obtained with the group of relatives fell between those of the celiac disease and control groups, while the recurrent diarrhea group overlapped the relatives and controls. The residual peptides were derived chiefly from the B-type subfractions (pH 6 eluates from SP Sephadex-C25 columns) of subfractions 1 and 2, obtained by ion-exchange chromatography of fraction 9. These subfractions are rich in glutamine/glutamic acid (45.0 and 35.7 molar% for 1B and 2B, resp.) and proline (24.0 and 19.4 molar% for 1B and 2B, resp.) and have a molecular weight (apparent) of not greater than 1,500 daltons. The results lend further support to the hypothesis of an enzyme deficiency in celiac disease. A partial enzyme deficiency may exist in some first-degree relatives and in some children with recurrent diarrhea but with histology of the small intestine within normal limits. Human lymphocyte antigen (HLA)-B8 was found not to be correlated with this deficiency, but, when the two factors are associated, they could be related to the manifestation and severity of celiac disease.

6250 EFFECT OF HYPEROSMOLAR STIMULI AND COELIAC DISEASE ON THE PERMEABILITY OF THE HUMAN GASTROINTESTINAL TRACT. (Eng.) Wheeler, P. G.; Menzies, I. S.; Creamer, B. (King's Coll. Hosp. Medical Sch., London, England). *Clin. Sci. Mol. Med.* 54(5):495-501; 1978.

Oral loads with different marker substances were used to assess gastrointestinal permeability in 18 normal subjects and 5 patients with celiac disease. Lactulose (molecular weight [MW] 342), raffinose (MW 504), stachyose (MW 666), and a fluorescein-labeled dextran (MW 3,000) were used as marker substances. Timed urinary recovery of these substances, which are not metabolized, was measured by quantitative papaer chromatography and direct fluorimetry, and the results were used as an indication of passive intestinal permeability. The results in healthy adults showed that permeability to these markers was dependent on molecular size, even after correction for aqueous diffusion differences, such that a profile of restricted permeability could be described for this range of markers. Interpretation in terms of conventional pore theory suggested the presence of more than one population of pores. Ingestion of solutions made hyperosmotic by inclusion of glycerol resulted in a large increase in permeability, in a pattern that suggested an increase in either the size or frequency of a range of smaller pores. A similar increase in permeability and alteration in the profile of restriction was found in patients with celiac disease. The significance of intestinal permeability must relate to loss of metabolically important plasma constituents or absorption of antigenic, carcinogenic, or other toxic substances. A hyperosmotic stress or celiac disease, might enhance this possiblity, and increased accessibility to gliadin or its toxic fractions might, in the latter case, provide a self-perpetuating pathogenic stimulus.

6251 COWS' MILK PROTEIN-SENSITIVE ENTEROPATHY: AN IMPORTANT FACTOR IN PROLONGING DIARRHOEA OF ACUTE INFECTIVE ENTERITIS IN EARLY INFANCY. (Eng.) Iyngkaran, N.; Robinson, M. J.; Sumithran, E.; Lam, S. K.; Puthucheary, S. D.; Yadav, M. (Dept. Pediatrics, Univ. Malaya, Kuala Lumpur, Malaya). *Arch. Dis. Child.* 53(2):150-153; 1978.

The possible role of cows' milk protein in prolonging diarrhea in very young infants with acute infective enteritis was studied in 14 infants, 9 under the age of 2 months and 5 older than 6 months. Bacterial pathogens (*Salmonella* and enteropathogenic *Escherichia coli*) were isolated from the stools of four infants from the younger age group. After appropriate initial treatment, the infants were maintained on a cows' milk protein-free formula. Six weeks later jejunal biopsies were performed befor and 24 hr after challenge with a low-lactose cows' milk protein formula. The immunoglobulin and complement levels in the serum and duodenal juice we also estimated at these times. Attempts to isola bacterial and viral pathogens in stools were agai made in all patients. The five older infants cli ically tolerated cows' milk protein, and their pr and postchallenge jejunal biopsies were within normal limits. However, moderate to severe histological changes were observed in the postchalle jejunal biopsies of all 9 infants under 2 months age; in addition, five of these infants developed diarrhea. These findings suggest that, in very young infants previously fed a cows' milk protein based formula who contract infective enteritis, the jejunal mucosa suffers damage when rechalleng with cows' milk protein.

57 DETECTION AND TREATMENT OF RECURRENT CANCER OF THE COLON AND RECTUM. (Eng.)

lch, J. P.; Donaldson, G. A. (Hartford Hosp.,
Jefferson St., Hartford, CT 06106). *Am. J. Surg.*
5(4):505-511; 1978.

series of 177 patients with recurrent colorectal
ncer treated at the Massachusetts General Hos-
tal is examined retrospectively. Two-thirds of
currences were observed by the second postopera-
ve year, and 15% of patients were asymptomatic.
lvic recurrences were usually attributable to
ctal or sigmoid tumors, whereas right-sided car-
nomas frequently spread to the liver. The most
mmon methods of clinical discovery of recurrence
cluded findings of abdominal and pelvic masses
7% and 11%, resp.), hepatomegaly (14%), and posi-
ve chest films (16%). The average survival after
scovery of recurrence was only 11 months, but 23
tients having reresections for cure lived an
erage of 33 months. Seven patients undergoing
resection for cure represented probable cures.
emotherapy with i.v. 5-fluorouracil (77 patients)
ovided poor palliation, but radiotherapy (54
tients) gave satisfactory relief of symptoms in
ny patients, particularly those with rectal or
colon lesions. A program of follow-up is sug-
sted since there is evidence that even the symp-
matic patient may be well-palliated or even cured
surgical resection of the recurrence or by pal-
ative therapy.

58 ADJUVANT RADIATION THERAPY IN COLORECTAL CARCINOMA.

(Eng.) Friedmann, P.; Park,
C.; Afonya, I. I.; Chabot, J. R.; Garb, J. L.;
e, O. T.; *et al.* (Baystate Medical Center, 759
estnut St., Springfield, MA 01107). *Am. J. Surg.*
(4):512-518; 1978.

series of 65 patients with adenocarcinoma of the
tum and rectosigmoid is reviewed. Thirty-two
tients had surgery alone (S group), 14 patients
erwent postoperative radiation therapy (PO group),
19 patients underwent preoperative radiation
rapy (PRO group). A moderate-dose program of
00 to 4,500 r was used. The PO treatment group
a higher incidence of stage C lesions (12/14
sus 7/32 in the S group and 5/19 in the PRO
up, $p<0.005$) and a higher recurrence rate (10/14
sus 4/32 in the S group and 5/19 in the PRO
up), but there were no statistically significant
ferences in survival (40% in the PO group and
in the S group at 24 months and 70% in the PRO
up at 30 months). Postoperative radiation thera-
in patients with stage C lesions did not prolong
e and is of little benefit. The PRO treatment
up tolerated the radiation very well, and there
e no major complications. Eight patients under-
t anterior resections in irradiated fields. Two
or anastomotic leaks subsequently healed spon-
eously. There were no pelvic recurrences in the
treatment group, and the incidence of lymph node
astases was 26% as opposed to 41% in the S group.
is concluded that preoperative moderate-dose
iation is not associated with increased risk of
bidity or mortality. It may be useful in reduc-
the incidence of lymph node metastases and pelvic recurrence. The effect on survival is not determined in this study.

6259 CLOSTRIDIUM DIFFICILE AND THE AETIOLOGY OF PSEUDOMEMBRANOUS COLITIS. (Eng.)

Larson, H. E.; Price, A. B.; Honour, P.; Borriello, S. P. (Clinical Research Center, Watford Road, Harrow, Middlesex HA1 3UJ, England). *Lancet* 1(8073): 1063-1066; 1978.

To demonstrate that a toxin of clostridial origin causes pseudomembranous colitis (PMC), bacterial isolates from 5 patients with histologically proven PMC, 11 healthy adults, 20 patients with other bowel disorders, and 8 healthy newborn babies were screened for toxin production. Seven strains of *Clostridium* from four PMC patients produced *in vitro* a toxin similar to that found in their fecal suspensions. These strains were identified as *C. difficile*. *C. difficile* was not isolated from any of the 31 healthy adults or patients with other bowel disorders, although it was found in five of eight neonates, and toxin was present in the feces of two of them. Strains from two of the patients induced a fatal enterocolitis when inoculated p.o. into hamsters pretreated with vancomycin. The *C. difficile* that produced the toxin *in vitro* was then re-isolated from the hamster cecal contents. These findings suggest that PMC results from infection with *C. difficile* and that previous antibiotic therapy produces susceptibility to infection.

6260 VILLOUS TUMORS OF THE RECTUM AND COLON: A PATHOLOGICAL, CLINICAL AND THERAPEUTIC STUDY AND REPORT OF 81 CASES. (Fre.)

Sarles, J.; N'Guyen, R.; Anfossi, G. (C.H.U., Hopital Nord, 13326 Marseille Cedex 3, France). *Ann. Chir.* 31(8): 699-705; 1977.

A series of 81 villous tumors occurring in 60 patients was analyzed pathologically, clinically, and therapeutically. Multiple tumors were present in 20% of patients. Degenerated tumors comprised 18.5% of the total (13 invasive cancers and 2 *in situ*). Tumors with a diameter less than 5 cm had degenerated in only 12.7% of cases, whereas those with a diameter over 5 cm were degenerated in 50% of cases; in addition, 67% of all degenerated tumors occurred in patients over 60 yr old. The chief symptoms included hemorrhage, abundant mucous discharge, and diarrhea. Pediculated tumors were removed with a diathermy loop through a sigmoidoscope with only 1/18 known recurrences. Sessile tumors within 10 cm of the anal margin were surgically removed by the perineal route, and recurrences were seen in 4/13 patients; in contrast, removal of high tumors by colotomy led to no recurrences. Segmental colectomies and abdominoperineal amputations were successful in six patients with invasive, large, or multiple sessile tumors. The authors suggest that posterior rectotomies should be used more frequently for large tumors within 10 cm of the anal margin to prevent recurrences. Malignant villous tumors treated by wide removal have an excellent prognosis.

6261 LYMPHOMA OF THE COLON: THE SPECTRUM OF RADIOLOGIC CHANGES. (Eng.) O'Connell, D. J.; Thompson, A. J. (Dept. Radiology [Box 429], Univ. Chicago, 950 East 59th St., Chicago, IL 60637). *Gastrointest. Radiol.* 2(4):377-385; 1978.

The radiographic findings of 34 patients with colonic lymphoma are reviewed. Thirteen patients had primary tumors (PT), while the remaining 21 had colonic involvement secondary to systemic disease (secondary tumors, ST). The radiologic features were mucosal nodularity (2/13 PT patients, 12/21 ST patients), endo-exoenteric mass (2/13 PT, 10/21 ST), intraluminal mass (7/13 PT, 1/21 ST), mural infiltration, and mesenteric invasion (1/13 PT and 1/21 ST in each of the latter 2 cases). One patient with diffuse mucosal nodularity developed acute colonic dilatation, while two other patients had pneumatosis coli secondary to local tumor depositions. Lymphoma is now a well-described complication of chronic ulcerative colitis, and a further case is described here. Although colonic lymphoma is a relatively rare tumor, the spectrum of radiologic changes reviewed here may enable a more accurate radiologic diagnosis.

6262 ENDOCRINE CELLS OF THE COLON IN HIRSCHSPRUNG'S AND CONTROL CHILDREN. (Eng.) Cristina, M. L.; Lehy, T.; Voillemot, N.; Arhan, P.; Pellerin, D.; Bonfils, S. (Hopital Bichat, F-75877 Paris Cedex 18, France). *Virchows Arch.* [*Pathol. Anat.*] 377(4):287-300; 1978.

To determine if any anomaly of the colonic cell population might accompany the interruption of the development of the myenteric plexus in congenital megacolon, the large intestine resected from six Hirschsprung's patients and surgical colonic biopsies from six control children were examined with light and electron microscopy. In light microscope studies, endocrine cell data were expressed as number of cells per unit area of mucosa using a quantitative method after argentaffin and Grimelius's argyrophilic techniques and an immunoperoxidase reaction with glucagon and somatostatin (SRIF) antisera. The number and frequency of endocrine cells did not differ significantly between the ganglionic and aganglionic segments of Hirschsprung's patients or between the latter and control children. Glucagon immunoreactive cells were, on the average, 5-6 times and 7-9 times more numerous than SRIF cells in the rectum and the sigmoid, resp. Ultrastructurally, five endocrine cell types were distinguished; four types are found in the normal human colon, while the fifth type, probably a transition type, apparently disappears in adults. This study has established the presence of endocrine cells along the entire distal colonic mucosa in Hirschsprung's disease.

6263 COLONIC MYOELECTRICAL ACTIVITY IN IRRITABLE-BOWEL SYNDROME. (Eng.) Sullivan, M. A.; Cohen, S.; Snape, W. J., Jr. (570 Maloney Building, Hosp. Univ. Pennsylvania, 3400 Spruce St., Philadelphia, PA 19104). *N. Engl. J. Med.* 298(16):878-883; 1978.

To determine the effect of a standard meal on colon ic myoelectrical and motor activity in the irritabl bowel syndrome and to determine the effect of a single dose of an oral anticholinergic drug (5 mg clidinium bromide) on this response, 10 patients with the irritable bowel syndrome and 21 normal co trols were studied. The patients showed a prolong increase in both colonic spike (p<0.05) and motor activity (p<0.05) after eating as compared with normal subjects. In the patients, the greatest in crease in spike activity over fasting levels occur red 30-80 min or longer after eating (p<0.005). Clidinium did not affect the frequency of colonic slow waves (early response) or the basal colonic spike and motor activity in response to a meal. H ever, the anticholinergic drug reduced the prolong postprandial colonic spike and motor response in t patients and also reduced the postprandial increas in colonic contractions at 3 cycles/min (p<0.05). These studies indicate that patients with the irritable bowel syndrome show an abnormally prolonge postprandial increase in colonic spike and motor activity. An anticholinergic drug reduces the duration and the magnitude of this abnormal coloni response.

LARGE INTESTINE

Ulcerative Colitis

312 RADIOGRAPHIC CHARACTERISTICS OF COLONIC
"MUCOSAL BRIDGES": SEQUELAE OF INFLAM-
ATORY BOWEL DISEASE. (Eng.) Hammerman, A. M.;
hatz, B. A.; Susman, N. (Jewish Hosp. St. Louis,
16 S. Kingshighway, St. Louis, MO 63108). *Radi-
logy* 127(3):611-614; 1978.

he occurrence of colonic "mucosal bridges" as
equelae to inflammatory bowel disease, previously
escribed pathologically and endoscopically, are
escribed radiographically using two case reports
a 35-yr-old man and a 33-yr-old woman). The radio-
raphic pattern is that of multiple, long, linear,
ranching band-like filling defects. In the first
ase, they demonstrated a constant appearance at
nnual examinations over a 10-yr period, indicating
he durable nature of these structures. The bridges
ere mucosal-covered bands up to 15 cm in length
average lenth, 4-6 cm) crossing the lumen. They
anged from 0.4-0.6 cm in diameter. The basic
isease process in this case was difficult to
lassify precisely (i.e., regional enteritis versus
lcerative colitis). In the second case, a patient
ith ulcerative colitis, the radiographic pattern
iggested mucosal bridges, and at colonoscopy, long
nflammatory polyps, thickened mucosal folds, and
ucosal bridges were seen. Any disease of the
olon with the propensity to develop deep ulcera-
ions may possibly form mucosal bridges.

313 SERUM LYSOZYME, SERUM PROTEINS, AND IM-
MUNOGLOBULIN DETERMINATIONS IN NONSPECIFIC
FLAMMATORY BOWEL DISEASE. (Eng.) El-Khatib, O.
; Lebwohl, O.; Attia, A. A.; Flood, C. A.; Stein,
A.; Sweeting, J. G.; *et al.* (Coll. Physicians &
Surgeons, Columbia Univ., New York, NY). *Am. J. Dig. Dis.* 23(4):297-301; 1978.

The usefulness of serum lysozyme determinations in the differential diagnosis of nonspecific inflammatory bowel disease (IBD) into ulcerative colitis (UC), Crohn's disease (CD), or ulcerative proctitis (UP) was analyzed in 101 IBD patients. In addition, the disease activity was assessed independently of the laboratory findings by prospective determination of the serum lysozyme and immunoglobulin levels and by serum electrophoresis. Patients' disease states were categorized as active or inactive by clinical signs and symptoms observed when the serum samples were drawn. Although the mean serum lysozyme concentration of patients with CD (10.5 ± 6.8 μg/ml) and UC (9.6 ± 4.1 μg/ml), determined by a standardized lysoplate method, was significantly greater than that of normal controls (6.0 ± 1.5 μg/ml, $p<0.05$), the results did not correlate with the diagnosis or with the degree of disease activity. Individually separated protein fractions and serum immunoglobulins also did not correlate with the serum lysozyme levels. This study indicates that measurement of the level of serum lysozyme in individual patients is not helpful in determining the cause or degree of activity of nonspecific IBD.

6314 ABSENCE OF K CELLS IN HUMAN GUT MUCOSA. (Eng.) Clancy, R.; Pucci, A. (Faculty Medicine, Univ. Newcastle, NSW, Australia). *Gut* 19(4):273-276; 1978.

To determine whether antibody-dependent cell-mediated cytotoxicity (ADCC) operates as a cause of tissue cell damage in inflammatory disease of the small and large bowel, cell suspensions of mucosal lymphocytes prepared from human gut resections or biopsies were assayed by two methods for ADCC. In the first method, the Chang hepatoma cell assay was used with rabbit anti-Chang cell antibody; in the second method, the Chang cells were coated with *Escherichia coli* lipopolysaccharide, and pooled sera from six normal sybjects shown to have agglutinating activity against the *E. coli* lipopolysaccharide were used. In both cases, ADCC was measured as the specific release of ^{51}Cr from the prelabeled target cells. Gut mucosal lymphocytes from normal subjects and subjects with ulcerative colitis, Crohn's disease, and colon carcinoma were examined by at least one of the methods; blood lymphocytes from each subject were used as controls. Whereas ADCC activity was regularly demonstrated in the blood lymphocytes of all subjects by both assays (specific cytotoxicity, 1-67%), ADCC activity was not detected with mucosal lymphocytes with either assay (0-1% specific cytotoxicity). The possibility that K-cell activity was masked by adsorbed blocking factors was examined by preincubating gut lymphocytes and by treating them with trypsin; blood lymphocytes were again used as controls. Neither treatment allowed the detection of meaningful K-cell activity in gut lymphocytes (0-3% specific cytotoxicity, compared with 0-12% with blood lymphocytes, 0% being recorded only after a 24-hr incubation and probably reflecting a short lifespan in cultures for K cells). It appears that cells capable of mediating ADCC cannot be isolated from either normal or inflamed human colon mucosa. This technique will facilitate the direct study of the cellular basis of mucosal defense mechanisms and the pathogenesis of mucosal disease in man.

6315 SIGNIFICANCE OF ANERGY TO DINITROCHLOROBENZENE (DNCB) IN INFLAMMATORY BOWEL DISEASE: FAMILY AND POSTOPERATIVE STUDIES.

(Eng.) Meyers, S.; Sachar, D. B.; Taub, R. N.; Janowitz, H. D. (Annenberg 23-02, Mount Sinai Sch. Medicine, New York, NY 10029). *Gut* 19(4):249-252; 1978.

To evaluate the pathogenetic significance of impaired cellular immunity in inflammatory bowel disease (IBD), the cutaneous responsiveness to dinitrochlorobenzene (DNCB) was measured in 58 patients with IBD (33 with Crohn's disease and 25 with ulcerative colitis), 63 of their clinically normal relatives, 24 additional ileitis and colitis patients who had undergone resection of all visibly diseased bowel, and 23 control subjects. Cutaneous anergy to DNCB was demonstrated among 70% of the patients with Crohn's disease and 48% of those with ulcerative colitis, compared with only 9% of controls ($p<0.001$). There was no increased incidence of anergy among either 44 first-degree relatives (7%) or 19 spouses (0%), nor was there any special proclivity toward anergy among six pairs of patients with familial inflammatory bowel disease. In Crohn's disease, anergy was still present after bowel resection in 6 of 10 patients, while in ulcerative colitis anergy was found after colectomy in only 2 of 14 patients. The data suggest that the immune defect in patients with IBD may be a secondary phenomenon. In ulcerative colitis, the defect appears to reverse after colectomy, but in Crohn's disease it persists despite resection. Thi finding is consistent with the observed tendency of Crohn's disease, but not ulcerative colitis, to inexorable postoperative recurrence.

6316 II. PREVALENCE OF PERIPHERAL ARTHRITIS, SACROILIITIS, AND ANKYLOSING SPONDYLITIS IN PATIENTS SUFFERING FROM INFLAMMATORY BOWEL DISEASE.

(Eng.) Dekker-Saeys, B. J.; Meuwissen, S. G. M.; van den Berg-Loonen, E. M.; de Haas, W. H. D.; Agenant, D.; Tytgat, G. N. J. (Amsterdam Cente for Rheumatic Diseases, Amsterdam, Netherlands). *Ann. Rheum. Dis.* 37(1):33-35; 1978.

To establish the prevalence of peripheral arthriti (PA), radiographic sacroiliitis (RSI), and ankylos ing spondylitis (AS) in patients with inflammatory bowel disease, 58 consecutive patients with ulcera tive colitis (UC) and 51 with Crohn's disease (CD) underwent a detailed rheumatological examination. In addition, all patients were screened for the presence of the antigen human lymphocyte antigen (HLA) B27. PA was found in 8 UC and 6 CD patient RSI was diagnosed in 5 UC and 6 CD patients, of whom 10 were asymptomatic, and AS was diagnosed i 2 UC and 2 CD patients. HLA B27 was found in 18. of the UC and 3.9% of the CD patients. One of the 11 patients with RSI and 2 of the 4 with AS had t HLA B27 antigen. PA, RSI, and AS are apparently frequent manifestations in patients with inflammatory bowel disease. Asymptomatic RSI in these patients appears to differ from idiopathic AS, both clinically and genetically. Evaluation of subjective rheumatological complaints, necessary for a confident diagnosis of AS, according to the New York criteria, is difficult during a flare-up of the inflammatory bowel process, as was shown in f CD cases with marked limitation of lumbovertebral function and chest expansion, but no radiological abnormalities of the sacroiliac joints.

6317 III. CLINICAL CHARACTERISTICS AND RESU OF HISTOCOMPATIBILITY TYPING (HLA B27) 50 PATIENTS WITH BOTH ANKYLOSING SPONDYLITIS AND FLAMMATORY BOWEL DISEASE.

(Eng.) Dekker-Saeys, J.; Meuwissen, S. G. M.; van den Berg-Loonen, E. de Haas, W. H. D.; Meijers, K. A. F.; Tytgat, G. J. (Amsterdam Center for Rheumatic Diseases, Ams dam, Netherlands). *Ann. Rheum. Dis.* 37(1):36-41; 1978.

To determine the genetic and clinical characteri tics of patients with both inflammatory bowel di ease (IBD) and ankylosing spondylitis (AS), a st was made, in cooperation with several gastroente ology and rheumatology centers, of 50 patients w either Crohn's disease (CD, 38 patients) or ulce ated colitis (UC, 12 patients), all 50 of whom a had AS (the latter diagnosis being established a cording to the New York criteria). Human lympho cyte antigen (HLA) B27 was positive in 20 CD and UC patients. These frequencies were statistical significant ($p<0.001$ or $p<0.01$) when compared t

ntrols examined in a separately published series.
e presence of HLA B27 was studied in relation to
inical parameters, such as first occurrence of
mptoms of AS or IBD, a history of peripheral
thritis, iridocyclitis, and a positive history of
or IBD. The patients were found to have hetero-
neous clinical features: at one end of the spec-
um, a group of cases was distinguished with the
pical characteristics of idiopathic AS, often
ing HLA B27 positive. At the other end, a smaller
oup of HLA B27-negative patients was observed,
th severe intestinal inflammatory pathology,
cking most of the typical clinical features of
iopathic AS ("secondary" form of AS). Finally,
tween these two extremes, a group of patients was
und with less pronounced clinical or genetic
aracteristics. These different clinical and his-
compatibility patterns suggest a mixed etiopatho-
nesis of AS in IBD patients. Such a "syndrome"
AS might harbor both idiopathic AS and forms of
"secondary" to the intestinal inflammatory path-
ogy.

18 CHRONIC ULCERATIVE COLITIS AND COLON CAN-
CER: CAN RADIOGRAPHIC APPEARANCE PREDICT
RVIVAL PATTERNS? (Eng.) James, E. M.; Carlson,
C. (Mayo Clinic, Rochester, MN 55901). *Am. J.*
ntgenol. 130(5):825-830; 1978.

enty-four patients with chronic ulcerative colitis
l colon carcinoma who underwent barium enema ex-
ination prior to the diagnosis of cancer were
idied to correlate the radiographic appear-
ce of the tumors with their biologic behav-
, as well as to assess the accuracy of the barium
ema in tumor detection. Of the radiographically
ected tumors, 65% displayed an annular infiltra-
e appearance, with the prime radiographic mani-
station being relative nondistensibility of the
olved segment. The remaining tumors had various
earances (nodular or polyploid; annular, bulky;
villous) more typical of noncolitic colon cancer.
ients with infiltrative lesions had a much poorer
gnosis than those with noninfiltrative lesions.
33 gross tumors described pathologically and/or
gically, only 70% were correctly detected by
ium enema. It is suggested that periodic barium
ma examinations are an unreliable means of fol-
ing patients with ulcerative colitis if malignant
degeneration is to be detected at an early and curative stage. Prophylactic proctocolectomy may be the best therapeutic approach.

6319 DEFICIENCY OF FREE SECRETORY COMPONENT (fSC) OF SALIVARY IgA IN INFLAMMATORY BOWEL DISEASE (IBD)--A FAMILY STUDY [Abstract]. (Eng.) Engstrom, J. F.; Sagawa, A.; Arvanitakis, C.; Abdou, N. I. (Kansas Univ. Sch. Medicine, Kansas City, KS). *Gastroenterology* 72(5, Part 2):1158; 1977.

6321 INCIDENCE OF FIRST HOSPITALIZATIONS FOR ULCERATIVE COLITIS, ULCERATIVE PROCTITIS, AND CROHN'S DISEASE IN BALTIMORE: A TEN-YEAR COMPARISON [Abstract]. (Eng.) Mendeloff, A. I.; Garagliano, C. F.; Lilienfeld, A. M. (No affiliation given). *Gastroenterology* 72(5, Part 2):1163; 1977.

6322 MORTALITY FROM ULCERATIVE COLITIS IN DENMARK 1960-1969. (Eng.) Kristensen, E.; Mosbech, J. (Copenhagen County Hosp., St. Elisabeth, 2300 Copenhagen, Denmark). *Scand. J. Gastroenterol.* 12(2):189-191; 1977.

6323 EVALUATION OF CANCER RISK IN CHRONIC ULCERATIVE COLITIS: PROGRESS REPORT OF A PROSPECTIVE STUDY [Abstract]. (Eng.) Levin, B.; Riddell, R. H. (Univ. Chicago Hosp., Chicago, IL). *Gastroenterology* 72(5, Part 2):1088; 1977.

See also, 6044, 6081, 6088, 6265, 6273, 6297, 6303, 6364, 6499, 6524, 6540.

PANCREAS

4 THE PANCREAS: A CORRELATION OF FUNCTION
AND STRUCTURE. (Eng.) Waye, J. D.;
er, M.; Dreiling, D. A. (Mount Sinai Sch. Medi-
e, City Univ. New York, New York, NY). *Am. J.*
troenterol. 69(2):176-181; 1978.

compare the diagnostic value of endoscopic pan-
atography with secretin tests obtained from the
e patients, 52 patients with or without pancre-
c disease were studied with both the secretin
t and endoscopic retrograde pancreatography
(ERCP). Pancreatic histopathology was obtained by exploratory laparotomy in half of these patients to permit correlation of histology with ERCP and the secretin test. Of 21 patients with normal secretin tests, 14 had no clinical evidence of pancreatic disease and a normal ERCP, 3 had normal ERCP consistent with acute pancreatitis (2) and recurrent acute pancreatitis (1), and 4 had beading of the pancreatic duct on ERCP and histologically proven chronic pancreatitis. Of 21 patients with secretin tests suggesting chronic pancreatitis, 17

such diagnoses were histologically proven (12/17 also had abnormal ERCP); the remaining 4 had normal ERCP and histological evidence was lacking. Of four patients with secretin tests showing hypersecretion and who had normal ERCP, diagnoses of chronic hepatitis (1), primary biliary cirrhosis (1), and chronic pancreatitis (1) were histologically proven, and the unconfirmed diagnosis of early alcoholic pancreatitis (1) was made. In six patients with secretin tests showing low volume, three had abnormal ERCP (2 had carcinoma, 1 had had partial pancreatic resection); of the three with normal ERCP, one had chronic pancreatitis with fibrosis, and two had normal pancreas at laparotomy. It is concluded that (1) secretory tests are the most sensitive indicators of chronic pancreatitis, although not all cases of chronic pancreatitis will be discovered by this test, (2) when secretory tests show low volume output, pancreatography is crucial in differentiating between malignant ductal obstruction or pancreatic replacement by fibrosis or atrophy, (3) histologic correlation with ductular structure and/or secretin function is frequently discordant, and (4) the secretin test and pancreatogram measure different parameters, and the use of both these complementary studies will lead to increased diagnostic accuracy and better understanding of pancreatic pathophysiology.

6325 CLINICAL AND STATISTICAL STUDIES ON CONGENITAL DILATATION OF THE BILIARY TRACT IN RELATION TO ANOMALOUS ARRANGEMENT OF THE PANCREATICOBILIARY DUCTS. (Eng.) Udaka, H. (Sch. Medicine, Tokushima Univ., Tokushima, Japan). *Tokushima J. Exp. Med.* 24(3/4):165-173; 1977.

Among 16 cases of congenital dilatation of the biliary tract seen over a 4-yr period, 6 were found to be complicated by anomalous arrangement of the pancreaticobiliary ducts, prompting a nationwide search for similar cases in Japan. Among 852 cases of congenital dilatation of the biliary tract collected from major medical institutions, 570 cases supplied satisfactory information for detailed analysis. The male:female ratio was 3:7. The incidence was high in childhood (245/570 with 63/245 at less than 1 yr of age and 172/245 at less than 5 yr of age). Anomalous arrangement of the pancreaticobiliary ducts was found in 183/570 cases. A new morphological classification of dilatation of the biliary tract is proposed (cystic, spindle, cylindrical, rosary, and diverticular dilatation), and an anatomical classification of anomalous arragements of the pancreaticobiliary ducts is offered: (1) the common bile duct flows into the pancreatic duct (118/183 cases), (2) the pancreatic duct flows into the common bile duct (38/183 cases), and (3) the common bile duct flows into the main pancreatic duct and an accessory pancreatic duct is present (12/183 cases). There were 15/183 cases in which the anomaly was too complex to be classified in this system. From the present clinical and statistical investigations, anomalous arrangement of the pancreaticobiliary ducts can be postulated as one of the etiological factors of the congenital dilatation of the biliary tract.

6326 MACROAMYLASEMIA AND OTHER CHRONIC NONSPECIFIC HYPERAMYLASEMIAS: CHEMICAL ODDITIES OR CLINICAL ENTITIES. (Eng.) Warshaw, A. L.; Lee, K. H. (Massachusetts General Hosp., Bosto MA 02114). *Am. J. Surg.* 135(4):488-493; 1978.

Because macroamylasemia has been regarded as an associated phenomenon in other primary diseases an only a coincidental biochemical oddity, its significance as a clinical entity (as a determinant o erroneous diagnosis and overtreatment) and perhaps as a genuinely symptomatic pathophysiologic proces was evaluated, and a new form of chronic hyperamylasemia is described. Seventeen patients with chronic hyperamylasemia (of whom 3 had alcoholic liver cirrhosis; 2, duodenal ulcer; 2, gallstones; and 1, leukemia) were studied using standard clinical and laboratory parameters, amylase/creatinine clearance ratios, and polyacrylamide gel electrophoresis of serum amylases. These patients, none of whom had evidence of pancreatic disease or othe specific source for the elevated serum amylase, fell into three groups: (1) normal serum isoamylase profile and normal amylase clearance (6 patients), (2) macroamylasemia and very low amylase clearance rates (9 patients), and (3) salivary-type hyperamylasemia and low amylase clearance ra (2 patients). It is postulated that the generalized hyperamylasemia in group (1) may be due to reduced extrarenal catabolism of amylase, a previously undescribed phenomenon. Seven of the nin patients in group (2) had recurrent epigastric pain. Evidence for an autoimmune basis of this entity is discussed. The entity in group (3) may really be macroamylasemia in which the macroamylase complex dissociated during analysis. Chroni hyperamylasemia is often not of pancreatic origin The assumption that the pancreas is at fault, especially if there is abdominal pain, may cause morbidity due to gross overtreatment.

6327 ANGIOGRAPHY OF PANCREATIC ARTERIOVENOUS MALFORMATION. (Eng.) Chuang, V. P.; Pulmano, C. M.; Walter, J. F.; Cho, K. J. (Univ. Kentucky Medical Center, Lexington, KY 40506). *Am. J. Roentgenol.* 129(6):1015-1018; 1977.

PANCREAS

Pancreatitis

33 GUIDELINES IN THE MANAGEMENT OF PATIENTS
WITH PANCREATIC ABSCESS. (Eng.) Paloyan,
; Simonowitz, D.; Bates, R. J. (Dept. Surgery,
niv. Chicago, Chicago, IL). *Am. J. Gastroenterol.*
)(1):97-100; 1978.

systematic approach to the management of patients
th pancreatic abscess is presented. The method
cludes an aggressive diagnostic approach relying
radiographic and ultrasound examinations and
lequate transperitoneal drainage of the abscess,
upled with gastrostomy and feeding jejunostomy.
e importance of nutritional support using an
emental diet administered through a jejunostomy
emphasized.

34 GLUCAGON VS ANTICHOLINERGICS IN THE TREAT-
MENT OF ACUTE PANCREATITIS: A DOUBLE-
IND CONTROLLED TRIAL. (Eng.) Gilsanz, V.; Oteyza,
P.; Rebollar, J. L. (Medical Sch., Universidad
mplutense de Madrid, Madrid, Spain). *Arch. Intern.
d.* 138(4):535-538; 1978.

test the therapeutic effect of glucagon on acute
ncreatitis and to compare the results with those
a control group treated with an anticholinergic,
patients with acute pancreatitis, evaluated for
verity according to uniform standards, were treat-
identically except that patients in one group re-
ived glucagon hydrochloride (group A) and those
the other, oxyphenonium bromomethylate (group B)
doses of 1 mg i.v. every 4 hr for 4 days. Each
the two homologous series comprised 31 patients,
d mortality was the same for both groups (3/31).
atistical comparison of both series showed no
gnificant differences in frequency of expected
mplications or in fall of serum amylase levels.
During treatment, serum calcium levels were significantly reduced in group A ($p<0.005$), and the duration of the abdominal pain was shortened ($p<0.05$). The volume of gastric aspirate was smaller in group B ($p<0.005$), and vesical catheterization proved necessary more frequently ($p<0.005$). Thus, similar results are obtained when glucagon or anticholinergics are employed in the treatment of acute pancreatitis, although secondary effects differ.

6335 THE ROLE OF PERITONEAL LAVAGE IN SEVERE ACUTE PANCREATITIS. (Eng.) Ranson, J. H. C.; Spencer, F. C. (New York Univ. Medical Center, 560 First Ave., New York, NY 10016). *Ann. Surg.* 187(5):565-575; 1978.

Clinical experience with the management of acute pancreatitis and an evaluation of the therapeutic efficacy of peritoneal lavage are presented in 103 patients with "severe" pancreatitis (28% mortality) who were separated from 347 with "mild" pancreatitis (0.9% mortality) by previously described early objective signs. Early treatment (day 0-7) of severe pancreatitis included peritoneal lavage through catheters placed nonoperatively in 18 patients (group A) and by catheters placed at laparotomy in 6 (group C). Early treatment of nonlavage patients with severe pancreatitis was by standard nonoperative measures in 61 cases (group B) and included early operation in 18 (group D). Lavage was continued for 48-96 hr, usually using 36-48 liters/24 hr of balanced isotonic dialysate fluid, and was uncomplicated. Lavage led to striking immediate clinical improvement and no lavaged patient (groups A and C) died during the first 10 days of treatment for pancreatitis. By contrast, 45% of deaths in nonlavaged patients (groups B and D) occurred during this early period, usually from cardiovascular or respiratory failure. Although lavage reduced mortality in subgroups of patients, ultimate overall survival was not affected (Group A, 83%; B, 84%; C, 33%; D, 33%). Late peripancreatic abscesses caused most deaths in lavaged patients. These data show that peritoneal lavage is a highly effective adjunct to the treatment for early complications of severe acute pancreatitis and dramatically reduces early mortality. Lavage does not prevent the late local sequelae of peripancreatic necrosis.

6336 PANCREATITIS IN CHILDHOOD. (Eng.) Buntain, W. L.; Wood, J. B.; Woolley, M. M. (Children's Hosp., 1601 Sixth Ave. South, Birmingham, AL 35233). *J. Pediatr. Surg.* 13(2):143-149; 1978.

All 30 cases of pancreatitis in children diagnosed at one institution during the period 1957-1972 are reviewed. Diagnosis was based on the clinical findings of pancreatic inflammation, laboratory confirmation with elevated serum and/or urinary amylase values, and in some cases surgical or postmortem evidence of peripancreatic fat necrosis and/or intramedullary fat necrosis with or without hemorrhagic manifestations. Four major classes of pancreatitis were seen and defined in children: traumatic (10 cases), systemic disease associated (7), drug-induced, caused by drug therapy for various life-threatening diseases (7), and chronic pancreatitis, with or without an anatomic abnormality (3). In addition, there were two cases of idiopathic acute pancreatitis and one of idiopathic acute relapsing pancreatitis. The overall mortality was 8/30, which compares unfavorably with the 12% mortality usually seen in adults with pancreatitis. If cases of traumatic pancreatitis are excluded, girls outnumber boys 5 to 1; patients ranged in age from 2 to 18 yr. A high index of suspicion is necessary to make the diagnosis, and this is very important if the mortality for pancreatitis in children is to be lowered. Awareness and consistent early aggressive intervention should increase the salvage rate. Pancreatitis is not as rare in the pediatric age group as has been commonly believed.

6337 THE FIRST 24 HOURS OF ACUTE PANCREATITIS: CHANGES IN BIOCHEMICAL AND ENDOCRINE HOMEOSTASIS IN PATIENTS WITH PANCREATITIS COMPARED WITH THOSE IN CONTROL SUBJECTS UNDERGOING STRESS FOR REASONS OTHER THAN PANCREATITIS. (Eng.) Drew, S. I.; Joffe, B.; Vinik, A., Seftel, H.; Singer, F. (Dept. Surgery, Univ. California, Los Angeles, CA 90024). *Am. J. Med.* 64(5):795-803; 1978.

Because the changes in biochemical and endocrine homeostasis in acute pancreatitis reflect both stress and the disease itself and because it is difficult to quantitate the magnitude of the stress response, two patient groups were compared. As a group, 20 patients with acute pancreatitis showed alterations in biochemical and endocrine homeostasis that differed from the metabolic reactions observed in 13 control patients undergoing stress for reasons other than pancreatitis. In patients with acute pancreatitis, hyperglycemia was associated with inappropriately low serum insulin levels ($p<0.005$). Plasma glucagon concentrations were markedly increased in the patients with acute pancreatitis and exceeded control values ($p<0.0001$) throughout the 24-hr study period. The lipolytic effect of the inadequate serum insulin concentrations, elevated blood cortisol levels, and hyperglucagonemia produced a rise in the levels of nonesterified fatt acid. Serum gastrin and growth hormone measurements remained within the normal range. Plasma parathyroid hormone and calcitonin concentrations were increased in both patient populations, although calcitonin levels in patients with pancreatitis were significantly lower than those in the control group ($p<0.001$). In patients experiencing a recurrent attack of pancreatitis, plasma glucagon levels were low ($p<0.005$) compared with levels in patients experiencing their first episode of acute pancreatitis. Appreciation of the metabolic derangements in acute pancreatitis that are independent of the normal metabolic changes that occur in response to stress will help to rationalize exogenous endocrine therapy and possibly the prognosti accuracy in this disease.

6338 ENTEROPEPTIDASE LEVELS IN DUODENAL JUICE OF NORMAL SUBJECTS AND PATIENTS WITH GASTROINTESTINAL DISEASE. (Eng.) Rinderknecht, H.; Nagaraja, M. R.; Adham, N. F. (Veterans Admin. Hosp., Sepulveda, CA 91343). *Am. J. Dig. Dis.* 23 (4):327-331; 1978.

To establish a baseline for the study of a possibl role of enteropeptidase in gastrointestinal disease in adults, enteropeptidase, trypsin, and chymotrypsin activities in basal and secretin (1 U/kg, i.v.)-stimulated duodenal juice of 20 normal adults and 15 patients with gastrointestinal disease were determined. All enzyme concentrations showed skew distributions, but fluctuations in the secretin-stimulated juices were less pronounced than in the basal secretions. Secretin administration had no influence on the release of enteropeptidase from human duodenal mucosa, but it resulted in a very small increase in secretion of pancreatic enzymes. Six of seven patients with chronic alcoholic pancreatitis or cancer of the pancreas exhibited highly significant elevations of enteropeptidase in their basal as well as secretin-stimulated duodenal juice (152 ± 51.6 and 163.4 ± 28.1 mIU/g protein, resp., compared with 66.6 ± 19.7 and 38.8 ± 6.0 mIU/g in normal controls and 129 ± 33.9 and 112 ± 22.5 mIU/g in patients with gastrointestinal disease). It is suggested that raised luminal enteropeptidase activit may be the result of pancreatic insufficiency or elevated blood glucagon concentrations.

6339 THE SPECTRUM OF COLONIC INVOLVEMENT IN PANCREATITIS. (Eng.) Grodsinsky, C.; Ponka, J. L. (Henry Ford Hosp., 2799 West Grand Blvd., Detroit, MI 48202). *Dis. Colon Rectum* 21(1 66-70; 1978.

Colonic involvement in pancreatitis is demonstrate

3 case histories selected from 14 patients who
d colonic involvement of varying severity. In
x patients, this complication occurred during the
rst attack of pancreatitis. Seven other patients
d recurrent pancreatitis, and one had no history
pancreatitis. Alcohol was the etiologic factor
12 cases. In seven patients, the colonic in-
lvement resolved spontaneously. Surgical inter-
ntion was required in the other seven cases. Ex-
rience with these patients suggests that colonic
volvement may be characterized by three patterns
anatomic involvement: (1) early adynamic or
calized paralytic ileus, (2) fibrosing or sten-
ing pericolitis, and (3) colonic necrosis and
stulization. In the first, the extent of in-
lvement is shown radiologically by the cut-off
gn, which quickly disappears in response to con-
rvative treatment. When the patient has stenosis
condary to fibrosing pericolitis that may be in-
stinguishable from malignancy, elective resection
indicated. When necrosis has led to fistuliza-
on producing massive bleeding, external drainage
the necrotic collection and proximal colostomy
y be the procedure of choice.

0 NECROSIS OF THE COLON SECONDARY TO PANCRE-
ATITIS. (Eng.) Thompson, W. M.; Pizzo,
V.; Kelvin, F. M.; Rice, R. P. (Duke Univ. Medi-
Center, Durham, NC 27710). *Am. J. Dig. Dis.*
Suppl. 5):92S-96S; 1978.

case of a 56-yr-old woman who developed radio-
phic evidence of transverse colon inflammation
condary to acute pancreatitis and who subsequently
veloped necrosis of the colon is reported. Six-
n years prior to the acute pancreatitis she had
a 90% gastrectomy and gastrojejunostomy. She
a mild diabetic, well-controlled on oral medi-
ion. One month after discharge following treat-
t for pancreatitis and severe inflammation of
colon, she presented with a 2-week history of
current severe abdominal pain; on the 10th hos-
al day, she had gross rectal bleeding and became
kedly obtunded. Abdominal radiographs revealed
dence of a pancreatic abscess and changes con-
tent with necrosis in the splenic flexure. Ex-
ratory laparotomy revealed a necrotic transverse
on with extensive abscess and fat necrosis in
upper retroperitoneal area. Despite transverse
ectomy, ileostomy, and drainage of the abscesses,
patient died on the second postoperative day.
hologic examination of the surgical specimen re-
led a markedly thinned colonic wall, numerous
sions of the mucosa, fibrinous adhesions, focal
crosis, acute inflammatory infiltrate and necro-
of the muscle cells of the muscularis, and nu-
ous thrombosed small vessels. Obvious findings
peritonitis were revealed at autopsy. The colon
crosis may have been due to a combination of the
semination of pancreatic enzymes in the trans-
se mesocolon and the development of the pancre-
c abscess. Because the clinical presentation of
hemic colitis and colon necrosis due to pancrea-
is may be masked by the signs and symptoms of
underlying disease, a contrast enema should be
formed in all patients suspected of having colon-
manifestations of pancreatitis.

6341 PANCREATITIS--A RARE COMPLICATION OF SCHONLEIN-HENOCH PURPURA. (Eng.) Puppala, A. R.; Cheng, J. C.; Steinheber, F. U. (7307 Rustic Valley, Dallas, TX 75248). *Am. J. Gastroenterol.* 69(1):101-104; 1978.

The case of a 54-yr-old woman who developed hemorrhagic pancreatitis as a complication of Schonlein-Henoch purpura is reported. One day after beginning p.o. tetracycline for an upper respiratory infection, she developed a rash over her legs and discontinued the medication. The next day, she presented with arthralgia of the left wrist and right elbow, nausea, epigastric pain, vomiting of coffee-ground material, rectal bleeding, weakness, and dizziness. The day after admission, she developed vague, colicky abdominal pain; on the second hospital day, new erythematous patches appeared over her forehead that were shown by biopsy to be a nonspecific perivasculitis. On the third hospital day, the patient developed severe epigastric pain and tenderness, had a serum amylase level of 340 Somogyi U/100 ml and a urine amylase excretion of 550 U/hr (normal maximum, 300 U/hr). A barium upper gastrointestinal x-ray showed thick duodenal and jejunal folds giving rise to a "stacked coin" appearance. The rash disappeared in 1 week; abdominal pain and fluctuating serum amylase and urine amylase excretion levels gradually decreased. A brief literature review of Schonlein-Henoch purpura is given. The patient had a history of upper respiratory infection and tetracycline treatment, both of which are implicated in the etiology of this syndrome. As there were no other etiological factors, the acute pancreatitis is viewed as a rare complication of the syndrome.

6342 SURGICAL MANAGEMENT OF CHRONIC PANCREATITIS. (Ita.) Petronio, R.; Vantini, I.; Marzoli, G. P.; Piubello, W.; Pederzoli, P.; Puchetti, V.; *et al.* (Clinica Chirurgica II, Universita di Padova, Sede di Verona, Via Mameli 20, Verona, Italy). *Minerva Med.* 68(30):2109-2121; 1977.

LIVER AND BILIARY TRACT

6351 α-FETOPROTEIN (AFP) IN BENIGN LIVER DISEASE: EVIDENCE THAT NORMAL LIVER REGENERATION DOES NOT INDUCE AFP SYNTHESIS. (Eng.) Alpert, E.; Feller, E. R. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 74(5, Part 1):856-858; 1978.

To determine whether the normal regenerating liver produces α-fetoprotein (AFP), 100 sera samples, obtained during the early postoperative period from 11 patients after partial hepatectomy, were assayed for AFP. In addition, AFP was measured in the sera of 199 patients with various forms of both benign viral and nonviral inflammation commonly associated with hepatic regeneration. None of the sera from the 11 posthepatectomy patients was AFP-positive by radioimmunoassay, despite clinical and biochemical recovery associated with normal liver regeneration. AFP was elevated in 29% of patients with acute hepatitis, 34% of patients with chronic active hepatitis, and in 75% of patients with massive hepatic necrosis. The mechanism and significance of AFP elevations in some patients with acute and chronic hepatitis is uncertain, but probably does not reflect normal liver regeneration.

6352 ASSESSMENT OF SEVERITY OF HEPATIC FUNCTIONAL IMPAIRMENT. (Eng.) Preisig, R.; Bircher, J.; Paumgartner, G. (Dept. Clinical Pharmacology, Univ. Berne, Murtenstr. 35, CH-3010 Berne, Switzerland). *Rend. Gastroenterol.* 9(3):228-233; 1977.

To improve the measurement of hepatic functional derangement in humans, animal models were investigated prior to human trials, and three techniques (hepatic uptake, metabolism, and excretion) useful for assessing the severity of liver disease in humans are described. Although sophisticated methods to assess hepatic uptake are available for animals, they are not yet applicable in humans. Yet it is possible to estimate an initial hepatic removal rate from the peripheral disappearance rat following different i.v. doses of indocyanine gre by the application of Michaelis-Menten kinetics. When the results obtained in patients with fatty liver or with cirrhosis are compared, the severit of functional impairment is evident from V_{max} and K_m values. Minor degrees of functional derangeme may escape detection with this technique. A brea test was developed to analyze hepatic metabolism by measuring hepatic microsomal function. A sing dose of 4-dimethyl-^{14}C-amino-antipyrine (DAA, 9 m kg p.o.) was given to 20 cirrhotics, and $^{14}CO_2$ was sampled intermittently up to 10 hr following administration. The disappearance rate of $^{14}CO_2$ activity from the breath (K_B) was directly correlated (r=0.90) with the disappearance rate of DAA from the plasma and proportional to the decrease in the galactose elimination capacity (a standard quantitative measure of a specific metabolic func tion), indicating that the breath test yields qua titative information on hepatic metabolic capacit A modification of the breath test uses uniformly labeled galactose instead of DAA. In a re-evalua tion of the BSP-disappearance curve, it was shown that the first exponential component (K_1) is a sensitive index to discriminate between normal subjects and patients with liver disease, and tha the second exponential component (K_2) provides quantitative assessment of excretory function. The quantification of selected metabolic and excretory functions will require additional study to become clinically applicable for the assessme of the severity of hepatic functional derangement

353 THE SELECTED BIOCHEMICAL AND IMMUNOLOGICAL EXAMINATIONS IN CHRONIC LIVER DISEASES
D THEIR RELATIONSHIP TO PATHOANATOMICAL FINDINGS
TAINED BY BIOPSY.

(Eng.) Passati, P.; Horejsi,
; Jezkova, Z.; Fassati, M. (District Medcare Cen-
er, Prague 9, Czechoslovakia). *Tijdschr. Gastro-*
terol. 20(3):177-190; 1977.

correlate biochemical and immunological indica-
rs of liver dysfunction with morphological and
stological changes, 135 patients with chronic
ver disease (≥2 yr duration) underwent liver bi-
sy and were classified according to five morpho-
gical types: steatosis, noncharacteristic histo-
gical findings, chronic hepatitis, liver cir-
osis, and ascitic liver cirrhosis. Of the series
laboratory tests performed, 17 biochemical in-
ces were grouped into six categories displaying
me similarity in feature or mutual dependence
rotein spectrum, turbidity, and flocculation;
sts for cholestasis; tests for liver cell in-
grity; chromosecretion tests; antibody deter-
nation tests; and other laboratory tests) and
aluated in relation to the morphological findings.
P retention and complete chromosecretion BSP
rve were the most specific and sensitive indica-
rs of functional liver damage; in chronic hepa-
tis, cirrhosis, and ascitic cirrhosis, values for
P excretion were 80%, 92%, and 100% greater than
rmal, resp. Damage to the integrity of the liver
ll, especially in chronic hepatitis and cirrhosis,
s reliably indicated by increased γ-glutamyl-
anspeptidase (γ-GTP), SGTP, and SGOT activities.
creased γ-GTP and alkaline phosphatase levels
re also related to biliary lesions. The detection
autoantibodies to liver, gallbladder, and bile
ct antigens, while not indicative of the severity
the lesion, was considered useful as an indicator
previous pathological events in the liver. Bio-
emical tests in conjunction with biopsy may be
lpful for the precise diagnosis of the severity
d character of liver damage and for the selection
d subsequent evaluation of a therapeutic regimen.

354 PLASMA LIPOPROTEIN ALTERATIONS AND MORPHOLOGIC CHANGES WITH LIPID DEPOSITION IN THE
IDNEYS OF PATIENTS WITH HEPATORENAL SYNDROME.

Eng.) Hovig, T.; Blomhoff, J. P.; Holme, R.; Flat-
ark, A.; Gjone, E. (Natl. Hosp. Norway, Oslo 1,
rway). *Lab. Invest.* 38(5):540-549; 1978.

lasma lipoproteins and morphological changes in the
idneys were studied in four patients with advanced
iver disease and progressive renal failure compat-
le with the diagnosis of hepatorenal syndrome.
l four patients had low plasma lecithin:cholester-
l acyltransferase activity, and the concentration
cholesteryl esters was markedly reduced. The
ain lipoprotein classes were abnormal with an in-
reased content of polar lipids. Electron micro-
copy of negatively stained lipoproteins from two
atients revealed large particles with layered mem-
ranes (700-2,000 A in diameter) corresponding to
he large molecular weight fraction of the low den-
ity lipoproteins. These structures were not pre-
ent in the low density lipoproteins from the other two patients. In the renal biopsy from one patient with layered membranes and in the necropsy specimen from the other patient with layered membranes, deposition of osmophilic material was found in the glomeruli (especially located subendothelially), in the basement membrane, and in the mesangial regions. The deposits were similar to those previously described in patients with familial lecithin:cholesterol acyltransferase deficiency and most probably represent cholesterol and phospholipids. It is suggested that the renal deposition of lipid may be related to the large molecular weight low density lipoprotein fraction and that the mechanisms involved in this lipid deposition are similar to those occurring in familial lecithin:cholesterol acyltransferase deficiency.

6355 TRANSVENOUS (TRANSJUGULAR) LIVER BIOPSY: AN EXPERIENCE BASED ON 100 BIOPSIES.

(Eng.) Lebrec, D.; Degott, C.; Rueff, B.; Benhamou, J. P. (Hopital Beaujon, 92110 Clichy, France). *Am. J. Dig. Dis.* 23(4):302-304; 1978.

Experience with transvenous (transjugular) liver biopsy in patients in whom percutaneous needle liver biopsy was contraindicated because of massive ascites and/or bleeding tendency is presented. This method consists of taking a liver specimen through a needle introduced into the liver parenchyma from the lumen of a hepatic vein. This procedure was attempted 104 times in 98 patients. A liver specimen was obtained in 100 of these 104 attempts; the tissue specimens were unfragmented and large enough to allow correct evaluation of liver architecture in 57 biopsies. The procedure was followed by no or only minor complications in all patients except one who suffered a fatal intraperitoneal hemorrhage in relation to perforation of the liver capsule; perforation was due to an excessive front rotation applied to the needle, a maneuver which therefore must be avoided. It is concluded that transvenous liver biopsy is a workable, efficient, and acceptably safe procedure for obtaining liver specimens in patients with massive ascites and/or bleeding tendency.

6356 MODIFICATION OF THE LONGMIRE PROCEDURE.

(Eng.) Cameron, J. L.; Gayler, B. W.; Harrington, D. P. (Johns Hopkins Hosp., Baltimore, MD 21205). *Ann. Surg.* 187(4):379-382; 1978.

Two modifications of the Longmire procedure of intrahepatic cholangiojejunostomy are described, and a successful application is reported. The first modification involves the preoperative placement under fluoroscopic control of a large Teflon catheter in the distal left hepatic duct to facilitate the identification and isolation of the duct at the time of surgery. The second modification is the use of a transhepatic silastic biliary stent positioned by utilizing the Teflon catheter. These modifications make the Longmire procedure technically much easier and should help insure long-term success in both benign and malignant strictures. This procedure was successfully employed in the treatment of a 22-yr-old woman who had developed stricture of the left hepatic duct and multiple adhesions in the porta hepatis following resection of the right hepatic lobe that had been fractured by blunt trauma. The patient is asymptomatic 7 months after surgery.

6357 MESOATRIAL SHUNT: A NEW TREATMENT FOR THE BUDD-CHIARI SYNDROME.

(Eng.) Cameron, J. L.; Maddrey, W. C. (Johns Hopkins Hosp., Baltimore, MD 21205). *Ann. Surg.* 187(4):402-406; 1978.

A new shunt procedure, the mesoatrial shunt, for decompression of the liver is described. A 56-yr-old woman presented with alcoholic cirrhosis and the Budd-Chiari Syndrome. Because of a thrombosed inferior vena cava, none of the standard portal-systemic shunts could be utilized for decompression of the engorged liver. A new shunt constructed by interposing a Dacron® graft between the superior mesenteric vein and the right atrium was performed. Portal pressure was reduced by the shunt from 30 cm of H_2O to 10 cm of H_2O. Patency has been confirmed postoperatively by catheterization and with angiopathy. The patient is asymptomatic with normal liver function tests nine months following the procedure. A surgical approach is outlined for symptomatic patients with the Budd-Chiari Syndrome that could result in improved survival in patients with this entity.

6358 CELL-MEDIATED CYTOTOXICITY IN CHRONIC ACTIVE LIVER DISEASE: A NEW TEST SYSTEM.

(Eng.) Vogten, A. J. M.; Hadzic, N.; Shorter, R. G.; Summerskill, W. H. J.; Taylor, W. F. (Univ. Hosp. Utrecht, Utrecht, Netherlands). *Gastroenterology* 74(5, Part 1):883-889; 1978.

An *in vitro* cytotoxicity system is described for studying patients with chronic active liver disease using as the target cells ^{54}Cr-labeled avian RBC coated with cell membrane lipoprotein extracted from human liver and, as the aggressors, mononuclear cells from peripheral venous blood. The method was tested in patients with liver diseases and in controls. Thirty of 62 patients with chronic active liver disease showed cytotoxicity in this test system as did 5 of 100 apparently healthy controls. In addition, mild cytotoxicity was shown by 2 of 8 patients with the primary biliary cirrhotic syndrome and 2 of 17 persons with other liver diseases. No specific antibody was added to the test system, and the cytotoxicity was inhibited by free lipoprotein, antilipoprotein, and by aggregated immunoglobulin. Cytotoxicity also was abolished by the depletion from the mononuclear cells of cells phagocytic for iron filings. The effect of depletion of these phagocytic cells was not restored by the addition of 2-mercaptoethanol. These findings add further evidence that autoimmune responses to liver tissue occur in many patients with chronic active liver disease and, importantly, also suggest that these may occur in some apparently healthy people.

6359 HEPATOCYTE DAMAGE INDUCED BY LYMPHOCYTES FROM PATIENTS WITH CHRONIC LIVER DISEASES, AS DETECTED BY LDH RELEASE.

(Eng.) Fernandez-Cruz, E.; Escartin, P.; Bootello, A.; Kreisler, M.; Segovia de Arana, J. M. (Scripps Clinic and Res. Foundation, 10666 North Torrey Pines Rd., La Jolla, CA 92037). *Clin. Exp. Immunol.* 31(3):436-442; 1978.

A cytoplasmic enzyme system was used in the study of the *in vitro* cytotoxic activity of human peripheral blood WBC against isolated liver cells in patients with chronic liver diseases. Lymphocytes from nine primary biliary cirrhosis and eight chronic active liver disease patients were shown to have an *in vitro* capacity to induce a cytolytic effect on isolated hepatocytes, as demonstrated by the enhanced release of LDH ($p<0.001$), a cytoplasmic marker enzyme. No significant LDH release was seen with control lymphocytes of 20 normal persons or with lymphocytes from 10 patients with alcoholic cirrhosis. A new, simple, and reproducible cytoplasmic enzyme system for the study of lymphocyte effector functions was demonstrated. These results corroborate, in a different assay system, that lymphocyte-mediated liver cell damage *in vitro* occurs in both primary biliary cirrhosis and chronic active liver disease.

6360 PRIMARY HEPATIC TUMOR.

(Eng.) Alpert, E.; Ferrucci, J.; Athanasoulis, C.; Malt, R. A.; Galdabini, J. (Massachusetts General Hosp., Boston, MA 02114). *Gastroenterology* 74(4):759-769; 1978.

Factors considered in the differential diagnosis of a primary hepatic tumor are discussed by several physicians. The patient was a 25-yr-old woman who had been suffering for 3 months with lower abdomina pain and had a large, hard, right upper quadrant mass. The patient had been taking oral contraceptives for 4 yr and had had a single episode of hepatitis 5 yr before the current illness. The differential diagnoses examined were focal nodular hyperplasia (FNH) and liver cell adenoma (LCA), bot benign tumors, and hepatocellular carcinoma. Neither history nor physical examination were useful in determining the nature of the liver mass. A computed tomographic liver scan using iodinated contrast material suggested that the lesion was not especially well-vascularized. Angiographic findings excluded LCA and indicated that the differential diagnosis involved FNH and hepatocellula carcinoma. On the basis of a high serum concentration of alpha-fetoprotein, which has not been detected in any patient with a benign liver tumor, the diagnosis of hepatocellular carcinoma was made. The diagnosis was confirmed following right hepati lobectomy. This patient is the fifth young person with hepatocellular carcinoma who has either been on birth control pills or has had an abnormality in steroid metabolism, suggesting the involvement of aberrant steroid metabolism in the genesis of these tumors.

6361 HEPATIC TUMORS OF INFANCY AND CHILDHOOD.

(Eng.) de Lorimier, A. A. (Sch. Medicin

niv. California, San Francisco, CA 94143). *Surg.*
lin. North Am. 57(2):443-448; 1977.

rimary tumors of the liver account for 1.5-2.0% of
nildhood cancers. Girls more commonly develop
ocal nodular hyperplasia (female:male, 3.4:1) and
emangioma (2:1), while boys develop hepatoblastoma
nd hepatocarcinoma 1.3 times more often than do
irls. The predominant symptom (in 90%) is an ab-
ominal mass; other complaints include anorexia,
eight loss, abdominal or lower chest pain, and
omiting. Laboratory findings may include anemia,
olycythemia, hyperlipemia, hypercholesterolemia,
levated levels of serum transaminase, alkaline
hosphatase, calcium, globulin, and bilirubin, and
ow serum levels of albumin, and phosphorus. Radio-
ogic studies, liver scan, ultrasonography, and
omputerized axial tomography are useful in evalu-
ting the tumor. Resection of the tumor should be
ttempted if at all possible because this is the
nly chance for cure (60% for hepatoblastoma and
5% for hepatocarcinoma). The tumor is confined to
he right lobe two to three times more often than
o the left. Involvement of both lobes or multi-
entric origin is seen in a third of the patients.
here is no correlation between the size of the mass
nd the prognosis. Operative mortality has been
5-33%, usually due to hemorrhage and transfusion
omplications. In patients in whom the tumor is un-
esectable or in whom there is residual tumor, radio-
herapy and chemotherapy may be beneficial. Re-
ression has been reported following the use of
everal drugs now undergoing clinical trials.

362 HISTOLOGIC AND CYTOLOGIC LIVER CHANGES IN 120 PATIENTS WITH MALIGNANT LYMPHOMAS.

Eng.) Roth, A.; Kolaric, K.; Dominis, M. (Dept.
hemotherapy, Sredisnji Institut za Tumore I Slicne
olesti, Ilica 197, 41000 Zagreb, Yugoslavia).
umori 64(1):45-53; 1978.

he frequency of liver involvement in malignant
ymphomas was determined to assess the value
f liver biopsy in the staging of malignant
ymphomas. Nonspecific liver changes were also
egistered. Percutaneous liver biopsy was per-
ormed in 120 patients with untreated malignant
ymphomas. There were 38 patients with Hodgkin's
isease, 42 with histiocytic lymphomas, and 40
ith lymphocytic lymphomas. All the biopsy spe-
imens were histologically and cytologically ana-
yzed. Positive liver findings (lymphomatous in-
iltration) were observed in 27.5% of patients with
ymphocytic lymphomas, 23.8% with histiocytic
ymphomas, and 7.8% with Hodgkin's disease. Liver
nvolvement in non-Hodgkin's lymphomas was signif-
cantly higher ($p<0.025$) than in Hodgkin's disease.
n the whole group of patients, there were non-
pecific liver changes: chronic persistent hepa-
itis (in 23), aggressive hepatitis (5), liver
teatosis (9), and liver hemosiderosis (4). It is
oncluded that liver involvement with lymphomatous
issue is more common in non-Hodgkin's lymphomas.
nowledge of this is relevant for clinical staging
nd the treatment program. These findings also
onfirm that percutaneous liver biopsy is a valuable diagnostic procedure in the staging of malignant lymphomas.

6363 INCIDENCE AND PATHOPHYSIOLOGY OF PULMONARY EDEMA IN FULMINANT HEPATIC FAILURE. (Eng.)

Trewby, P. N.; Warren, R.; Contini, S.; Crosbie, W. A.; Wilkinson, S. P.; Laws, J. W.; *et al.* (King's Coll. Hosp., Denmark Hill, London, SE5, England). *Gastroenterology* 74(5, Part 1):859-865; 1978.

Since pulmonary edema is common in fulminant hepatic failure, its frequency, its clinical effects, and the results of various treatment measures were analyzed. In addition, the respective roles of heart failure and of cerebral edema in the development of pulmonary edema were investigated. Thirty-seven of 100 consecutive patients with fulminant hepatic failure had clinical and radiological evidence of pulmonary edema. None had clinical evidence of left heart failure, and the pulmonary artery wedge pressure measured in 12 patients was normal. Similarly, there was no evidence to incriminate renal failure, endotoxemia, or hypoalbuminemia. However, there was a significantly higher incidence of pulmonary edema in patients with cerebral edema ($p<0.05$), suggesting either a central origin for the pulmonary edema or common factors predisposing to edema in both sites. An additional local factor may have been the presence of intrapulmonary vasodilatation. Detailed isotope studies in 11 patients showed a significantly increased ($p<0.01$) pulmonary extravascular water volume in the patients with pulmonary edema, which was in keeping with the severity of the radiological changes. Although the overall mortality was higher in those patients with pulmonary edema than in those without, the difference was not significant, and early ventilation with positive and expiratory pressure achieved adequate oxygenation in all but three patients.

6364 HEPATIC-PORTAL VENOUS GAS IN ADULTS: ETIOLOGY, PATHOPHYSIOLOGY AND CLINICAL SIGNIFICANCE. (Eng.)

Liebman, P. R.; Patten, M. T.; Manny, J.; Benfield, J. R.; Hechtman, H. B. (Boston Univ. Medical Center, Boston, MA 02115). *Ann. Surg.* 187(3):281-287; 1978.

The etiology, pathophysiology, and clinical significance of hepatic-portal venous gas (HPVG) in 60 previously reported cases are reviewed, and 4 new cases, occurring in adults, are presented. HPVG appears as a branching radiolucency extending to within 2 cm of the liver capsule. HPVG is associated with necrotic bowel (72%), ulcerative colitis (8%), intra-abdominal abscess (6%), small bowel obstruction (3%), and gastric ulcer (3%). Mucosal damage, bowel distention, and sepsis predispose to HPVG. The current mortality rate of 75% represents an improvement from previous experience. Analysis of survivors indicates that the finding of HPVG requires urgent surgical exploration except when it is observed in patients with stable ulcerative colitis.

6365 EFFECT OF CHENODEOXYCHOLIC ACID ON SERUM AND BILIARY LIPIDS IN PATIENTS WITH HYPERLIPOPROTEINEMIA.

(Eng.) Angelin, B.; Einarsson, K.; Leijd, B. (Karolinska Institutet, Stockholm, Sweden). *Clin. Sci. Mol. Med.* 54(4):451-455; 1978.

To study the effects of chenodeoxycholic acid therapy on serum and biliary lipid levels in hyperlipoproteinemia, chenodeoxycholic acid was administered to seven type IIa, eight type IIb, and eight type IV patients in a daily dose of 750 mg (1.9 mmol) for 3 months. The serum cholesterol and triglyceride concentrations were determined at 4-week intervals; cholesterol remained unchanged, whereas triglycerides decreased 15-20%. In 17 patients, biliary lipids were studied. The proportion of chenodeoxycholic acid in the bile increased from 28.8 ± 1.5 to 72.4 ± 3.6% ($p<0.001$) with reciprocal decreases in cholic and deoxycholic acids ($p<0.001$). Lithocholic acid and ursodeoxycholic acid increased significantly (from 0.2 ± 0.2 to 1.7 ± 0.4%, $p<0.005$ and 0.2 ± 0.2 to 3.2 ± 0.7%, $p<0.001$, resp.). Bile saturation with cholesterol decreased and correlated negatively with the proportion of chenodeoxycholic acid in biliary bile acids ($r=-0.67$, $p<0.001$) but positively with serum triglycerides ($r=+0.48$, $p<0.01$). It is concluded that chenodeoxycholic acid treatment in hyperlipoproteinemia is associated with a parallel fall in serum triglycerides and biliary cholesterol and thus may prove to be a useful adjunct in hypolipemic treatment.

6366 ORAL CONTRACEPTIVES AND FOCAL NODULAR HYPERPLASIA OF THE LIVER: TWO CASE REPORTS WITH ELECTRON-MICROSCOPIC STUDIES.

(Eng.) Balazs, M.; Gergely, R.; Kostic, Sz. (Janos Hosp., Diosarok u. 1, H-1125 Budapest, Hungary). *Acta Hepatogastroenterol. (Stuttg.)* 25(2):111-118; 1978.

Case histories are presented for two women (aged 26 and 36 yr) who had been on oral contraceptives for 2 and 6 yr, resp., and who developed focal nodular hyperplasia of the liver. In both cases, the tumors were discovered as subsidiary findings during cholecystectomy. The diagnosis was confirmed histologically and in one case the tumor was studied electron microscopically. The most outstanding feature of the electron microscopic study was abnormal vascularization. It is hypothesized that abnormal regeneration in the circumscribed areas of the liver is responsible for the disturbed microcirculation. Radical removal of the tumor and discontinuing oral contraceptives are recommended.

6367 JAUNDICE DURING PREGNANCY.

(Fre.) Darnis, F. (Hopital Saint-Antoine, 184, rue du faubourg Saint-Antoine, 75012 Paris, France). *Rev. Prat. (Paris)* 27(53):3683-3692; 1977.

Jaundice during pregnancy is classified into types, normal changes in the liver due to pregnancy are discussed, and three varieties of jaundice in pregnancy (recurring cholestasis, acute liver steatosis, and viral hepatitis) are described. Jaundice occurring during pregnancy may be caused or exacerbated by the pregnancy itself, such as recurring cholestasis or acute liver steatosis, or it may be coincidental, as with viral hepatitis, which causes 70% of all icterus during pregnancy. Cholestasis, which usually recurs with increasing severity durin successive pregnancies, affects women with a genetic predisposition towards cholestasis triggered by the high hormonal levels during the third trimester. Such women should never take oral contraceptives, since these may cause the same problem. The disease is almost always benign in the mother, and the jaundice and pruritus resolve spontaneously after parturition; however, fetal prematurity approaches 50% and fetal mortality is over 15%. Acut hepatic steatosis occurs during the third trimester of the first pregnancy. A severe icterus accompanied by hepatomegaly, hemorrhagic syndrome, and encephalopathies leads almost always to the expulsion of a dead fetus followed in a few days by the death of the mother. Massive doses of tetracycline have been implicated in some cases, but the similarity to Reye's syndrome suggests a genetic deficiency in ornithinetranscarbamylase activity. Viral hepatitis contracted during the first trimester is usually benign to mother and child, but when it occurs during the third trimester it may cause premature births in 50% of cases. The frequency of viral transmission to the fetus is practically nil during the first trimester, 25% during the second, and 80% during the third. Passive immunization of the newborn is recommended when the mother either has hepatitis B (HB) or is a chronic carrier of the HB surface antigen.

6368 HYPERPLASIA AND PROLAPSE OF HEPATOCYTES INTO HEPATIC VEINS DURING LONGTERM METHY TESTOSTERONE THERAPY: POSSIBLE RELATIONSHIPS OF THESE CHANGES TO THE DEVELOPMENT OF PELIOSIS HEPATI AND LIVER TUMOURS.

(Eng.) Paradinas, F. J.; Bull, T. B.; Westaby, D.; Murray-Lyon, I. M. (Charing Cross Hosp. and Medical Sch., London W6, England). *Histopathology* 1(4):225-246; 1977.

The pathological changes in liver biopsies from 10 patients (4 female transexuals and 6 impotent men) after treatment with 150 mg methyltestosterone dail for periods of up to 3 yr are reported; in additio changes in a hemihepatectomy specimen from a femal transexual who developed a liver adenoma after 37 months of this treatment are presented. Hepatocyte hyperplasia and mild focal sinusoidal dilatation was found in most cases. In some cases, there were microcysts and dissociation of hepatocytes. In nine patients, there was accumulation of hepatocytes between the endothelium and the supporting collagen of hepatic vein, which often resulted in either partial occlusion of their lumina or disruption of their walls. These vascular changes do not appear to have been reported before. It is postulated that a single pathological process--hyperplasia, perhaps related to the anabolic effect of methyltestosterone--could be partly responsible both for the formation of cysts through mechanical obstruction of hepatic veins and for the formation of nodules and tumors.

9 ERYTHROPOIETIC PROTOPORPHYRIA: HEPATIC
CIRRHOSIS. (Eng.) Cripps, D. J.; Gold-
b, S. S. (1300 University Ave., Madison, WI
06). *Br. J. Dermatol.* 98(3):349-354; 1978.

er pathology and function were studied in 12
ients with erythropoietic protoporphyria (EPP).
dle liver biopsies in 3 of 11 patients showed
d portal or periportal fibrosis without evidence
abnormal liver function. The 12th patient died
m hepatic cirrhosis and failure at the age of 11
the youngest yet reported. He was not suspected
pending liver disease until 3 months before death.
quantity of protoporphyrin present in his liver
approximately 5.75% of total liver weight.
al liver disease in EPP has occurred in 13 pa-
nts described in the literature, 7 men and 6
en, in which the mean age of death was 38 yr.
seriousness of hepatic complications in EPP
gests that patients with EPP should have reg-
r assessment of hepatic function.

0 WILSON'S DISEASE, PRESENTING AS CHRONIC
ACTIVE HEPATITIS. (Eng.) Scott, J.;
lan, J. L.; Samourian, S.; Sherlock, S. (Royal
e Hosp., London, NW3 2QG, England). *Gastroen-
ology* 74(4):645-651; 1978.

clinical course and prognosis of 17 patients
h Wilson's disease (mean age 12 years) who pre-
ted with clinical, biochemical, and morphological
tures similar to those of chronic active hepa-
is (CAH) are discussed. Neurological dysfunc-
n was evident in only three patients (mean age,
hr); Kayser-Fleischer rings were absent in eight
ients (mean age, 9.5 yr), and the serum cerulo-
smin and copper levels were normal in three pa-
nts with severe hepatic failure. Smooth muscle,
ochondrial, antinuclear, and hepatitis B surface
igen antibodies were negative in all patients.
levels of serum aminotransferases and γ-glo-
ins were elevated in all patients. Cirrhosis
present on initial liver biopsy in 15 patients.
pite D-penicillamine therapy (1.0 to 3.0 g
ly), four patients died within 3 weeks of di-
osis from fulminant hepatic failure associated
h hemolysis. A further five patients died with-
2 yr as a result of hepatic failure (3 patients),
iceal hemorrhage (1), and a lupus-like syndrome
. A sustained improvement was observed in eight
ients who remain well (mean survival time, 7
with near normal liver function tests and inac-
e hepatic histology. Wilson's disease patients
senting as CAH frequently exhibit atypical fea-
es: Kayser-Fleischer rings and neurological
function can be absent and both serum cerulo-
smin and serum copper can be normal especially
there is severe hepatocellular necrosis. As a
ult, diagnosis of Wilson's disease may be de-
ed, and once cirrhosis is established this form
Wilson's disease can have a poor prognosis de-
te D-penicillamine therapy. It is essential,
refore, that the diagnosis of Wilson's disease
excluded in all patients with CAH and chronic
enchymal liver disease of unknown etiology so
t an optimum treatment response to D-penicill-
ne can be achieved.

6371 HEPATIC AND VENA CAVAL INJURIES. (Eng.) Madding, G. F.; Lim, R. C.; Kennedy, P. A. (Sch. Medicine, Univ. California, San Francisco, CA 94143). *Surg. Clin. North Am.* 57(2):275-289; 1977.

The evaluation and treatment of hepatic and vena caval injuries are reviewed. Blunt injuries, as compared to stab or bullet wounds, frequently cause the most serious derangement of liver integrity. The peripheral venous hematocrit and abdominal paracentesis are useful in evaluating acute liver injury, while angiography and liver scans are not. The techniques used in the control of bleeding from liver injuries dictate, to a significant degree, the morbidity and mortality associated with the injury and include the use of gauze packs placed over the site of injury, suturing the individual vessels, resectional debridement, and rarely, sublobar resection. If metal fragments are present and readily accessible, they should be removed; but if extensive surgery would be required, they are best left in place. Subcapsular hematoma, if encountered at surgery, should be opened, followed by control of bleeding points, and removal of any pulpified liver. Retroperitoneal hematomas should be left alone unless expanding or bleeding. In cases where injury to the portal vein cannot be adequately repaired, it may be acutely ligated with safety. Injuries to the intrahepatic portion of the inferior vena cava with extensive liver parenchymal damage and lacerations of the major hepatic veins cause the majority of immediate deaths. Various types of antibiotics are sometimes used as solutions for irrigating the peritoneal cavity before wound closure, and broad-spectrum antibiotics started before or during surgery should be continued postoperatively.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

6415 THE ORGANELLE PATHOLOGY AND DEMONSTRATION OF MITOCHONDRIAL SUPEROXIDE DISMUTASE DEFICIENCY IN TWO PATIENTS WITH DUBIN-JOHNSON-SPRINZ SYNDROME. (Eng.) Peters, T. J.; Seymour, C. A. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Clin. Sci. Mol. Med.* 54(5):549-553; 1978.

To discover what, if any, enzyme deficiencies are involved in the Dubin-Johnson-Sprinz syndrome, analytical subcellular fractionation and marker enzyme microassays were used to study hepatic organelle pathology in liver biopsy specimens from two patients with the syndrome and from seven controls. Total (unfractionated) marker enzyme activities were very similar in the patients and controls except for a threefold increase in the activity of the lysosomal enzyme *N*-acetyl-β-glucosaminidase (2.03 ± 0.28 versus 7.55 and 6.64 mU/mg protein in the controls and 2 patients, resp.) and small increases in the activities of the three plasma membrane marker enzymes, alkaline phosphatase, 5'-nucleotidase, and leucyl-2-naphthylamidase (1.35 ± 0.17, 2.55, and 2.89; 13.7 ± 2.4, 18.3, and 20.9; and 1.28 ± 0.17, 3.98, and 3.69 mU/mg protein in the controls and 2 patients, resp., for each enzyme, resp.). When organelle marker enzymes were examined by sucrose density gradient centrifugation for the distribution of particulate enzyme activities, several differences between patients and controls were revealed. The distributions of acid phosphatase and *N*-acetyl-β-glucosaminidase varied between the two groups, with a marked decrease in lysosomal median density in the patients. In the controls, superoxide dismutase activity was largely soluble (remaining in the starting layer) with a distinct particulate peak (5-10% of total activity) at a position corresponding to that of malate dehydrogenase, but this distinct mitochondrial peak was absent in the patients. There was also a marked decrease in the median density of the endoplasmic reticulum marker, neutral α-glucosidase, in the patients. It is hypothesized that superoxide dismutase inhibits the formation of lipid peroxides and thus lipofuscin pigments by preventing the interaction of free O_2^- radicals with fatty acid components of membrane lipids. When lysosomes degrade mitochondria (these organelles have a half-life of 10 days), the accumulated lipofuscin is transferred to the lysosomes where it remains in increasing quantities, being re atively undegradable. The source of the melanin a of the impairment of conjugated bilirubin excretio in Dubin-Johnson-Sprinz syndrome is still not clea

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

6417 BOTRYOMYCOSIS AS AN OBSTRUCTIVE HEPATIC DISEASE. (Eng.) Bagby, G. C., Jr.; Gunning, J. J. (Veterans Admin. Hosp., Sam Jackson Park, Portland, OR 97207). *Arch. Intern. Med.* 138 (3):472-473; 1978.

The case of a previously well patient who initiall had apparent hepatitis due to *Pseudomonas aerugino* that spread hematogenously to involve both lungs is presented. The patient, a 20-yr-old man, presented with malaise, anorexia, dark urine, scleral

erus, diarrhea, and mild abdominal pain. The
ient rapidly developed both obstructive biliary
miliary pulmonary disease. Cultures of hepatic
sue grew *Pseudomonas*, but this was thought to
a contaminant. A liver scan showed a filling
ect. *P. aeruginosa* appeared in the sputum and
ne cultures as well as cultured lung tissue.
laparotomy, there was hepatosplenomegaly, small
enteric microabscesses, and small, white nodular,
m lesions beneath the hepatic capsule. All
tures of pus from multiple abscesses and of
atic tissue grew *P. aeruginosa*. The patient re-
nded to drainage of the abscesses and to genta-
in therapy. Twelve months postoperatively, all
er function studies, including liver scans and
i.v. cholangiogram were normal. Although the
sative organism in this case probably arose
m normal intestinal flora, the mode of trans-
sion to the liver is unknown. Nonetheless,
s case exemplifies the previously described
gressive subacute course of disseminated botryo-
osis, the lack of underlying host defense ab-
malities, and the importance of tissue diagnosis
special stains and culture of the involved organs.

8 MASSIVE HEPATIC NECROSIS ASSOCIATED WITH
DANTROLENE THERAPY. (Eng.) Donegan, J.
Donegan, W. L.; Cohen, E. B. (Milwaukee County
eral Hosp., 8700 West Wisconsin Ave., Milwaukee,
53226). *Am. J. Dig. Dis.* 23(Suppl. 5):48S-52S;
8.

case of a 53-yr-old woman who had been treated
the neurological symptoms of multiple sclerosis
4 months with dantrolene (200 mg. q.i.d.), Vis-
il (25 mg, q.i.d.), and Dalmane (30 mg before
iring) and who developed jaundice, ascites,
ressed pulmonary function, and oliguria is pre-
ted. Despite i.v. fluid therapy, diuretics,
ibiotics, parenteral salt-poor albumin, and
amins A, D, and K, the patient's condition de-
ned progressively, and she died in hepatic and
al failure on the 9th hospital day. An autopsy
ealed that the liver architecture was markedly
torted by extensive parenchymal necrosis and
t the reticulin framework was collapsed although
re was little fibrosis. The remaining parenchy-
cells exhibited fine vacuolization, intracellu-
cholestasis, and formation of pseudogranular
uctures, many of which contained bile plugs. A
erate inflammatory infiltrate was present in the
ules, consisting of both lymphocytes and granulo-
es, and the Kupffer cells contained phagocytized
ris. The usual lobular pattern of the liver was
rred. Esophageal varices and 2,700 ml of ascites
e present. The kidneys showed gross and micro-
pic changes compatible with acute tubular necro-
. Although the hepatocellular necrosis was rela-
ely nonspecific, in the absence of other causes
this damage, the authors believe the injury to
e been caused by dantrolene.

9 HOW SAFE IS ISONIAZID? (Eng.) Thompson,
J. E. (Health Commission of New South
Wales, 86-88 George St., Sydney, New South Wales 2000, Australia). *Med. J. Aust.* 1(3):165-169; 1978.

To determine the safety of isoniazid (INH) for the treatment or chemoprophylaxis of tuberculosis in Australian patients, the complications of INH treatment were studied in 1,033 patients who had received INH for at least 18 months with or without other drugs. Hepatitis developed in 25 patients; this was attributed to rifampicin (15 cases), infectious hepatitis (3 cases), INH alone (3 cases), INH possibly exacerbating chronic liver disease (2 cases), and multiple drug treatment (2 cases). Central nervous system disorders (mainly peripheral neuropathy) due to INH occurred in 12 patients, all of whom were over the age of 40 yr. Hypersensitivity to INH developed in 12 patients. When the risk of hepatitis was compared with the risks of developing or dying from tuberculosis, it was found that the benefits of INH chemoprophylaxis outweighed the risks, particularly in patients who were less than 50 yr of age. The findings suggest that, in an Australian population, INH can still be regarded as an extremely safe drug, particularly in nonalcoholic patients, and the safest drug available for the chemoprophylaxis of tuberculosis.

6420 HEPATIC DYSFUNCTION FOLLOWING METHYPRYLON INTOXICATION. (Eng.) Loiudice, T. A.; Buhac, I.; Peng, S. K.; Dillard, P. (Albany Medical Coll., Albany, NY 12208). *Am. J. Dig. Dis.* 23 (Suppl. 5):33S-37S; 1978.

The case history of a 63-yr-old man who developed hepatic dysfunction following methyprylon intoxication is presented. The patient attempted suicide by ingesting 29 capsules (8.7 g) of methyprylon. At the time of admission (5 hr after ingestion), the patient was comatose and responsive only to deep pain. He was treated by gastric lavage and i.v. fluids, began to awaken 4 hr after admission, and became fully awake without signs of physical or neurological deficit after 48 hr. Whereas initial laboratory studies had been normal, studies on the fifth hospital day indicated abnormal liver function (SGOT, 177 mU/ml; alkaline phosphatase, 576 mU/ml; total bilirubin, 1.8 mg/dl; 5'-nucleotidase, 29.3 mU/ml) that persisted 2 weeks. Liver scan was normal. A liver biopsy on the 14th hospital day revealed hydropic swelling of hepatic cells, cellular disarray, disruption of hepatic cords, and the presence of periportal inflammation and regenerating hepatocytes. Evidence of a moderate cholestasis was present, but there was no evidence of centrilobular necrosis. The patient continued his recovery and was discharged 1 month after admission. Although methyprylon must now be added to the list of drugs capable of causing hepatic injury, its wide usage in the treatment of insomnia indicates that this toxicity must be extremely rare.

6421 NON-MECHANICAL HEMORRHAGE IN SEVERE LIVER INJURY. (Eng.) Clagett, G. P.; Olsen,

W. R. (Walter Reed Army Medical Center, Washington, DC 20012). *Ann. Surg.* 187(4):369-374; 1978.

Experience with coagulopathy, or nonmechanical bleeding, associated with severe liver injury is reviewed in an attempt to elucidate its pathogenesis and formulate methods of prevention and treatment. Coagulopathy complicated the operative course of 17 of 33 patients suffering severe liver trauma. The highest incidence of nonmechanical hemorrhage (12/18) occurred in patients undergoing anatomic lobectomy. Serial hemostatic parameters were assessed and thrombocytopenia was the most striking abnormality in patients with nonmechanical hemorrhage. The degree of thrombocytopenia was directly correlated with the number of blood transfusions administered ($r=-0.79$, $p<0.001$). The mean operative blood transfusion requirement was significantly greater in patients with nonmechanical hemorrhage (25.1 ± 2.87 U) than in those without (12.2 ± 1.83 U, $p<0.001$). The bulk of this transfusion was given before the onset of clinically overt coagulopathy. Massive transfusion of stored blood was felt to be the most important factor in causing nonmechanical hemorrhage. Convincing evidence for disseminated intravascular coagulation was lacking, and abnormal fibrinolysis was infrequent and mild when observed. Although uneventful in most, in six patients nonmechanical hemorrhage resulted in excessive blood transfusion, unnecessary operation, or death. Infusions of platelet concentrate, fresh frozen plasma, and fresh blood were used to treat successfully most cases of nonmechanical hemorrhage. In all cases, these components were not started until nonmechanical hemorrhage was clinically apparent. The value of prophylactic use of blood components is stressed. Because of troublesome side-effects associated with the use of prothrombin complex concentrates, these agents are contraindicated in patients with severe liver injury. After receiving concentrates, one patient developed severe hypotension leading to ventricular fibrillation, two developed transient thrombocytopenia, and two others demonstra multiple pulmonary microthrombi at autopsy, a fi ing not observed in autopsied patients not recei the concentrates. Prothrombin concentrates appe to be contraindicated in patients with severe li injury.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

6425 HEPATITIS A VIRUS INFECTION IN FULMINANT HEPATITIS AND CHRONIC ACTIVE HEPATITIS. (Eng.) Rakela, J.; Redeker, A. G.; Edwards, V. M.; Decker, R.; Overby, L. R.; Mosley, J. W. (Rancho Los Amigos County Hosp. [1100 Bldg.], 7601 E. Imperial Highway, Downey, CA 90242). *Gastroenterology* 74(5, Part 1):879-882; 1978.

Studies were carried out in 72 patients with fulminant hepatitis and 35 with chronic active hepatitis to determine whether hepatitis A virus (HAV) could be implicated in the etiology of these diseases. Among the 42 patients with hepatitis B surface antigen (HBsAg)-negative fulminant disease, seroconversion was detected by immune adherence hemagglutination for antibody to HAV (anti-HAV) in 3 of 10 survivors, as well as an increasing anti-HAV score by immune electron microscopy. In the 32 HBsAg-negative nonsurvivors, 3 patients were found wit anti-HAV detectable by immune electron microscop and radioimmunoassay, but not by immune adherenc hemagglutination. The latter cases were classif as presumptively attributable to HAV. In 10 survivors among 30 HBsAg-positive patients with fulminant disease, no instances of anti-HAV seroconversion were detected. In the 20 HBsAg-positive nonsurvivors, 1 case had anti-HAV detectable by immune electron microscopy and radioimmunoassay not by immune adherence hemagglutination. This case was also considered to be presumptively cau by HAV. Anti-HAV was studied in patients with chronic active hepatitis. The incidence of anti-HAV in 13 HBsAg-positive cases was 31%, which did not differ from the 32% found in 22 HBsAg-negati

ses. There was one seroconversion for anti-HAV
one patient with HBsAg-negative chronic active
atitis, but this appeared to be an epiphenomenon.
al shedding of HAV patients with HBsAg-negative
onic active hepatitis was not present in any of
patients tested. The failure to find HAV in fe-
specimens from patients with chronic active
atitis does not preclude an etiological relation-
p between this agent and chronic disease, but it
resents initial evidence against that hypothesis.
finding that the frequency of anti-HAV is the
e in patients with HBsAg-positive as HBsAg-
ative chronic active hepatitis argues against a
nificant role of HAV in these cases.

26 PREVALENCE OF HEPATITIS A AND B INFECTIONS IN MULTIPLY TRANSFUSED THALASSAEMIC PA-

NTS. (Eng.) Papaevangelou, G.; Frosner, G.;
nomidou, J.; Parcha, S.; Roumeliotou, A. (Athens
. Hygiene, Athens 602, Greece). *Br. Med. J.*
11):689-691; 1978.

lassemia patients who receive regular blood
nsfusions and who live in an area in which hepa-
is is highly endemic were studied to determine
prevalence of hepatitis A virus (HAV) and hepa-
is B virus (HBV) infections in these patients
to evaluate the role of blood transfusions in
atitis A and B transmission. Evidence of HBV
HAV infections was sought in 148 multiply
nsfused patients with homozygous B-thalassemia
in healthy controls (2,040 for HBV and 217 for
). The prevalence of the HBV surface antigen
sAg) or antibody to it (anti-HBs) was signif-
ntly higher (p<0.001) in patients (90.5%) than
controls (17.3%) and it increased with the number
blood transfusions (82.5, 93.5, and 92.5% for
ients with <100, 100-199, and ≥200 transfusions,
p.). In contrast, the prevalence of antibody to
was significantly lower (p<0.001) in patients
n in controls (59.9%) and it decreased with the
ber of blood transfusions (21.0, 15.2, and 8.4%
patients with <100, 100-199, and ≥200 trans-
ions, resp.). Anti-HAV was significantly more
valent (p<0.05) among the controls who were pos-
ve for HBsAg or anti-HBs (28/36) than among pa-
nts who were positive for HBsAg or anti-HBs
/134). These results support the view that blood
nsfusion does not play any appreciable part in
nsmitting HAV. Indeed, regular blood transfusion,
re donors almost all have HAV antibody, seems
give protection against infection.

7 SEROLOGIC AND ANIMAL INOCULATION STUDIES OF A COMMUNAL OUTBREAK OF VIRAL HEPATITIS,

E A. (Eng.) Barker, L. F.; Dienstag, J. L.;
enz, D. E.; Purcell, R. H.; Wong, D. C.; Fein-
ne, S. M.; *et al.* (Div. Blood and Blood Products,
eau Biologics, 8800 Rockville Pike, Bethesda, MD
14). *Am. J. Med. Sci.* 274(3):247-253; 1977.

a from individuals in an outbreak of viral hepa-
is in a multifamily household, probably spread
contaminated food, were studied for antibodies
hepatitis A virus (anti-HAV), and selected acute
phase sera were inoculated into marmosets, to establish the etiology of this outbreak. Testing for anti-HAV was done by the immune adherence hemagglutination (IAHA) method, and the value of this procedure was assessed. Significant rises in anti-HAV titers between acute and convalescent sera occurred in all of 15 individuals in the outbreak who experienced serum enzyme elevations and in 1 of 14 individuals whose serum enzyme levels remained normal. The remaining 13 individuals in the latter group had antibody levels in both early and late sera compatible with residual immunity from prior HAV infections and correlating with resistance to reinfection. Groups of marmosets were infected with acute phase sera from two of the cases; in both instances the inoculated sera contained substantial levels of anti-HAV. The marmosets developed specific anti-HAV seroconversions as well as enzyme elevations. The results are indicative of the value of the IAHA test for establishing the etiologic agent in an outbreak of hepatitis. This study adds intrafamily spread to the already serologically established settings of HAV transmission.

6428 PREVALENCE OF HEPATITIS B IN A HIGH-RISK SETTING: A SEROLOGIC STUDY OF PATIENTS AND STAFF IN A PEDIATRIC ONCOLOGY UNIT.

(Eng.) Tabor, E.; Gerety, R. J.; Mott, M.; Wilbur, J. (Bureau Biologics, Bldg. 29, Rm. 311, 8800 Rockville Pike, Bethesda, MD 20014). *Pediatrics* 61(5): 711-715; 1978.

The prevalence of serologic markers for hepatitis B virus (HBV) was evaluated among 188 patients and 158 employees in a pediatric oncology unit. Evidence of past or present HBV infection was detected in 33 patients and in 25 employees. The prevalence was higher among patients receiving chemotherapy (19%) than among those not receiving chemotherapy (7%). The prevalence of HBV serologic markers, while much higher than generally found among healthy children in the United States, was low compared to previously reported prevalences in such settings, and may reflect the use in recent years of blood and blood products screened by "third generation" methods (radioimmunoassay and reversed passive hemagglutination) for hepatitis B surface antigen and the use of all volunteer blood donors. This prevalence suggests that there may be less urgent need for the use of hepatitis B immune globulin and hepatitis B vaccine (when it becomes available) in oncology units than had been anticipated from earlier data in oncology units.

6429 TRANSMISSION OF HEPATITIS B VIRUS INFECTION BY TRANSFUSION OF FROZEN-DEGLYCEROLIZED RED BLOOD CELLS.

(Eng.) Alter, H. J.; Tabor, E.; Meryman, H. T.; Hoofnagle, J. H.; Kahn, R. A.; Holland, P. V.; *et al.* (Blood Bank Dept., Bldg. 10A/ Rm. 1E33, Clinical Center, NIH, Bethesda MD 20014). *N. Engl. J. Med.* 298(12):637-642; 1978.

Chimpanzees were used to determine the ability of prior freezing of RBC to prevent the transmission of type B post-transfusion hepatitis.

Four units of human whole blood were each inoculated with 10^6 infectious doses of hepatitis B virus. Although all units became hepatitis B surface antigen (HBsAg) negative after freezing and deglycerolization, hepatitis B virus infection developed in all four chimpanzees when these units were transfused. Two of these chimpanzees had only serologic evidence of infection, including the development of HBsAg and antibody to both the hepatitis B surface and core antigens; in these animals, the incubation periods were prolonged (24 to 25 weeks). In contrast, the other two animals also had elevated levels of SGPT (peaks of 190 and 461 IU/l) and had a more rapid onset. There was no hepatitis B virus infection in two nontransfused controls. The results do not support the use of frozen RBC for the prevention of post-transfusion hepatitis. titis.

6430 PREVENTION OF NEONATAL HEPATITIS B INFECTION BY HIGH-DOSE HEPATITIS B IMMUNE GLOBULIN. (Eng.) Dosik, H.; Jhaveri, R. (Jewish Hosp. and Medical Center of Brooklyn, 555 Prospect Pl., Brooklyn, NY 11238). *N. Engl. J. Med.* 298(11):602-603; 1978.

The cases of two infants and their mother, who was a chronic hepatitis B surface antigen (HBsAg) carrier, are presented. The first child, a boy, developed fatal hepatitis at 3 months of age. Postmortem examination revealed that the child was HBsAg-positive, and the mother was discovered to be an asymptomatic HBsAg carrier. In the second child, a girl, HBsAg and antibody to HBsAg were negative on umbilical cord blood and capillary blood taken 2 hr after birth. She was treated with 5 ml of hepatitis B immune globulin on the day of birth and every 5 weeks for 6 months. HBsAg remained negative, and titers of antibody to HBsAg were consistently above 1:100 during treatment. Eight months after the last dose of hepatitis B immune globulin, the child remained antigen-negative and antibody-positive, with a normal growth pattern. The results in this patient and in many patients in the literature suggest that multi-injection therapy with hepatitis B immune globulin is indicated in infants of HBsAg-carrier mothers.

6431 T LYMPHOCYTE-MEDIATED CYTOTOXICITY IN HBsAg-POSITIVE LIVER DISEASE. (Eng.) El Sheikh, N.; Osman, C. G.; Cullens, H.; Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London S.E. 5, England). *Clin. Exp. Immunol.* 31(2):158-165; 1978.

Lymphocyte cytotoxicity assays were used to investigate T lymphocyte cytotoxicity in hepatitis B surface antigen (HBsAg)-positive liver disease, using HBsAg-coated RBC as target cells. When lymphocytes from 23 patients with acute hepatitis were tested, cytotoxic T cells were demonstrable during the recovery phase, but not in the first 3 weeks of the illness. However, when these same lymphocytes were extensively washed, cytotoxicity was then detected in all the patients, even at the time of presentation. In patients with HBsAg-positive chronic
liver disease, the results with the standard assa
were largely within the normal range, but, again,
with extensive lymphocyte washing, cytotoxicity w
detected in all of the patients with untreated
chronic active hepatitis and in five of six with
more minor histological lesions. The results in
five carriers with normal liver histology were co
pletely different, cytotoxicity remaining undetec
able even after the extensive washing pocedure.
The results suggest that blocking factors, possib
antigen or antigen-antibody complexes, could be
interfering with the detection of sensitized T ce
in patients with acute and chronic hepatitis but
that there is a true absence of sensitization to
HBsAg in healthy carriers with normal liver histology.

6432 HEPATITIS B SURFACE ANTIGEN IN HUMAN TE
(Eng.) Darrell, R. W.; Jacob, G. B. (E
ward S. Harkness Eye Inst., 635 W. 165th St., New
York, NY 10032). *Arch. Ophthalmol.* 96(4):674-676
1978.

Tears collected from 18 patients with hepatitis B
surface antigen (HBsAg)-positive serum and from 1
controls without HBsAg were tested to determine
whether the antigen can be transmitted via this
blood product. The tears were collected either
with a standard Schirmer test-strip or with a sof
contact lens. HBsAg was present in 10 of the 18
subjects with serum HBsAg. These results demonstrate that there is a risk of transferring hepatitis B virus infection by tonometers or soft con
tact lenses contaminated by HBsAg. Infection fro
body secretions, entry of HBsAg through the conjuctiva, infection among medical personnel, and
techniques of reducing hepatitis B virus infectio
are briefly reviewed.

6433 ANTIBODY TO HEPATITIS B SURFACE ANTIGEN
IN HAEMOPHILIACS ON LONG-TERM THERAPY W
SCOTTISH FACTOR VIII. (Eng.) Burrell, C. J.; Bl
S. H.; Ramsay, D. M. (Edinburgh Medical Sch., Edi
burgh, Scotland). *J. Clin. Pathol.* 31(4):309-312
1978.

Thirty-five patients with hemophilia A were stud
clinically and serologically in 1971-2 and 1975-
for evidence of hepatitis B infection to relate
the findings to the type and frequency of replace
ment factor VIII. One patient had clinical hepatitis B, and a further eight patients showed ant
body responses to hepatitis B surface antigen (H
consistent with exposure to HBsAg during this pe
No evidence for HBsAg exposure was found in 14 p
tients, while the remaining 12 patients had high
titers of antibody to HBsAg at both times so tha
no inferences could be drawn about HBsAg exposur
All patients had received exclusively replacemen
factor VIII material prepared locally from HBsAg
screened voluntary Scottish blood donations. Fr
the details of the therapy given, the rate of HB
seroconversion in these patients was calculated
represent about 0.3 HBsAg-containing donations p

00 donations. The findings should provide both
guide to the likelihood of seroconversion to
i-HBs positivity after factor VIII replacement
m similar defined sources and a basis for com-
rison of this material with commercial factor
I preparations.

4 SUBTYPES OF HBsAg AMONG HEPATITIS PATIENTS.
(Eng.) Ukkonen, P. (Dept. Virology, Univ.
sinki, Helsinki, Finland). *Scand. J. Infect.*
. 10(1):11-14; 1978.

um samples from 94 Finnish hospital patients
h hepatitis B were investigated for subtypes of
atitis B surface antigen (HBsAg), and these sub-
es were correlated with clinical data. The pa-
nts were divided into groups according to whether
y were drug abusers (31%), had some other in-
ased risk of contracting hepatitis (36%), or had
apparent indication of exposure. There were sig-
icant differences between the mean ages of the
ients and the clinical form of the disease as
l as the subtype of HBsAg. Patients with chronic
er disease or subtype *ad* were older than those
h acute hepatitis ($p<0.01$) or subtype *ay*
0.00002), resp. The drug abusers were the
ngest group. Subtype *ay* predominated in pa-
nts with acute hepatitis (77%). All drug
sers had the *ay* subtype. Of 11 patients with
onic liver disease, 10 had the *ad* subtype.
e of seven hepatitis cases associated with blood
nsfusion had subtype *ay*, although this deter-
ant has not been detected among Finnish non-
d blood donors. These results suggest that
od donors who incubate hepatitis B (HBsAg not
detectable) are an important source of trans-
ion hepatitis.

5 DUALITY OF HEPATITIS B e ANTIGEN IN SERUM
OF PERSONS INFECTED WITH HEPATITIS B VI-
: EVIDENCE FOR THE NONIDENTITY OF e ANTIGEN WITH
UNOGLOBULINS. (Eng.) Takahashi, K.; Imai, M.;
akawa, Y.; Iwakiri, S.; Mayumi, M. (Jichi Medi-
Sch., Tochigi-ken 329-04, Japan). *Proc. Natl.
d. Sci. USA* 75(4):1952-1956; 1978.

entitites of hepatitis B e antigen (HBeAg)
ivity physicochemically different from
h other, demonstrated in the sera of per-
s infected with hepatitis B virus, are des-
bed. One was associated with a molecule that
ecipitated in 1.33 M ammonium sulfate solution,

was larger than IgG, had an electrophoretic mobility in the β- to γ-globulin regions, and had an isoelectric point of approximately pH 5.7. In contrast, the other HBeAg activity was associated with a molecule that was soluble in 1.33 M ammonium sulfate solution, was smaller than IgG, and had an electrophoretic mobility in the α-globulin region and an isoelectric point at pH 4.8. In spite of their marked physicochemical differences, a line of antigenic identity was clearly observed for them when they were tested against antibody to HBeAg by a double immunodiffusion method. The HBeAg activity associated with the large molecule was completely removed by an affinity column of anti-IgG, whereas the activity of the small molecule was not. These results indicate that, in the serum, HBeAg exists as a molecule smaller than IgG and also in association with IgG.

6436 HEPATITIS B ANTIGEN--A SURVEY IN A MAJOR METROPOLITAN HOSPITAL. (Eng.) Luey, K. (Bristol Royal Infirmary, Bristol BS2 8HW, England). *Aust. N.Z. J. Med.* 7(4):394-399; 1977.

6437 APPLICATION OF A SCREENING TEST FOR ANTIBODY TO HEPATITIS B CORE ANTIGEN. (Eng.) Cohen, B. J.; Cossart, Y. E. (Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *J. Clin. Pathol.* 30(8):709-713; 1977.

6438 AN ENZYME-LINKED IMMUNOSORBENT-ASSAY TEST FOR HEPATITIS B SURFACE ANTIGEN. (Eng.) Vandervelde, E. M.; Cohen, B. J.; Cossart, Y. E. (Central Public Health Lab., Colindale Ave., London NW9 5HT, England). *J. Clin. Pathol.* 30 (8):714-716; 1977.

6439 BLOOD COAGULATION STUDIES IN PREGNANT PATIENTS WITH INFECTIVE HEPATITIS. (Eng.) Dube, B.; Bhattacharya, S.; Sinha, V. N.; Pandey, L. K.; Dube, R. K. (Inst. Medical Sciences, Banaras Hindu Univ., Varanasi, India). *Br. J. Obstet. Gynecol.* 84(8):592-599; 1977.

LIVER AND BILIARY TRACT

Chronic Hepatitis

0 CHRONIC HEPATITIS: A PROBLEM FOR THE
PATHOLOGIST. (Eng.) Scheuer, P. J. (Roy-
Free Hosp., Pond St., London NW3 2QG, England).
topathology 1(1):5-19; 1977.

histological classification of chronic hepatitis

is reviewed. The accepted histological categories of chronic hepatitis are chronic persistent hepatitis (CPH) and chronic active or aggressive hepatitis (CAH). A third form, chronic lobular hepatitis (CLH), encompasses those cases in which the lesion is predominantly within the lobules and in which portal and periportal inflammation are mild. International agreement on a reproducible and rational nomenclature of chronic hepatitis is still far from complete. CPH is characterized by portal inflammation. This category may need subdivision on the basis of immunological studies. CAH should be regarded as a complex rather than a single disease, and it is important to specify the etiology and pathological components in each instance. The concept of CAH must be altered to incorporate the lesion of bridging hepatic necrosis (BHN). Piecemeal necrosis, accompanied by inflammatory infiltration, is considered to be the most important of the various pathogenetic factors in CAH, but BHN probably plays a significant part in accelerating the development of cirrhosis. An excessive portal and periportal inflammatory reaction, with or without BHN, in a liver biopsy taken during the course of an acute hepatitis helps to predict a possible chronic course.

6441 CHRONIC ACTIVE HEPATITIS IN JERUSALEM: COMPARISON BETWEEN HBsAg-NEGATIVE AND HBsAg-POSITIVE CASES.

(Eng.) Shouval, D.; Penchas, S.; Sandler, S. G.; Mansour, D.; Eliakim, M. (Hadassah Univ. Hosp., Jerusalem, Israel). *Am. J. Gastroenterol.* 69(1):70-80; 1978.

To establish the etiology and the clinical and laboratory characteristics of chronic active hepatitis (CAH), 43 patients with biopsy proven CAH were studied with special reference to the presence or absence of hepatitis B surface antigen (HBsAg). Evidence of hepatitis B virus (HBV) infection (HBsAg and/or antibody to HBsAg [anti-HBs]) was found in 26 cases. Thus, HBV is probably the most important etiologic factor of CAH in the Jerusalem area. Fifteen patients were HBsAg-positive. This group was characterized by a higher frequency of male patients of Sephardic origin, a relatively frequent acute hepatitis-like onset, early presence of cirrhosis and portal hypertension, and relative rarity of skin rashes, thyroid involvement, and cholelithiasis. L.E. cells, cryoglobulin, paraprotein, and positive Kahn-Wassermannn tests were not found, and antimitochondrial antibodies were less common in this HBsAg-positive group. The mean level of serum albumin was lower while IgG and IgA levels were higher. Mortality was 7% during a mean follow-up period of 4.4 yr. The antigen-negative group was characterized by a higher prevalence of women of Ashkenazic origin, insidious onset, and more frequent presence of skin rashes, thyroid disease, and cholelithiasis. Peripheral lymphomonocytosis, high IgM levels, and antimitochrondrial antibodies were also more common. All cases with L.E. cells (mature neutrophilic polymorphonuclear WBC, which has phagocytized a spherical, homogeneous-appearing inclusion), cryoglobulin, paraproteinemia, and positive Kahn-Wassermann tests were in this gorup. Anti-HBs antibodies were present in 42% of the cases. Mortality was 29% during a mean follow-up period of 5.4 yr. Linear discriminant analysis with 10 variables (sex, mode of onset, skin rash, levels of serum albumin, IgA, and IgM, degree of BSP retention, presence of L.E. cells, antimitochondrial antibodies, and positive Kahn-Wassermann tests) classified correctly 100% of 12
cases that fulfilled the necessary criteria. Sex
ethnic origin (Ashkenazic or other), and presence
of thyroid disease classified correctly 85%
of 33 cases, thereby permitting a bedside classification with a high degree of credibility.

6442 LYMPHOCYTE CYTOTOXICITY IN CHRONIC ACTI HEPATITIS: EFFECT OF THERAPY AND CORRE- LATIONS WITH CLINICAL AND HISTOLOGICAL CHANGES.

(Eng.) Cochrane, A. M. G.; Moussouros, A.; Smith
A.; Portmann, B.; Eddleston, A. L. W. F.; William
R. (King's Coll. Hosp. and Medical Sch., Denmark
Hill, London, England). *Gut* 19(4):308-314; 1978.

Lymphocyte cytotoxicity for rabbit hepatocyte cul
tures was studied in patients with hepatitis B su
face antigen (HBsAg)-positive and -negative chron
active hepatitis, before and after immunosuppress
therapy. Before treatment, the cytotoxicity stud
ies in all of 15 patients with HBsAg-positive and
-negative hepatitis showed positive results in al
cases. After immunosuppressive therapy, cytotoxi
ty became negative and remained negative, in four
of nine patients followed serially. In 51 patien
established on therapy for periods from 3 months
to 12 yr, cytotoxicity was negative in 19, and al
patients are currently alive. However, in the re
maining 32 patients in whom cytotoxicity was posi
tive, there have been 11 deaths ($p<0.025$). Cyto-
toxicity remained persistently positive in 12 of
15 patients followed serially, and persistently
negative in 7 of 9. Cytotoxicity showed a signi-
ficant association with histological disease acti
ity ($p<0.0005$), especially with the extent of pie
meal necrosis ($p<0.01$), but not with biochemical
tests of liver function, immunoglobulins, or autc
bodies. The basis of this cytotoxicity test is a
antibody-dependent cell-mediated autoimmune reac-
tion directed against a liver specific protein, a
the results suggest that in some cases immuno-
suppressive therapy is followed by control of thi
reaction. It may be possible to stop therapy in
these patients, but in those in whom the reactior
continues, as shown by continuing cytotoxicity,
the prognosis is not as good, and the use of othe
drug schedules would seem worthy of trial.

6443 ANTIBODY TO HEPATITIS B CORE ANTIGEN I CHRONIC ACTIVE HEPATITIS.

(Eng.) Bor
P.; Coursaget, P.; Goudeau, A.; Degott, C.; Maupa
P.; Benhamou, J. P. (Hopital Beaujon, 92118 Clic
France). *Br. Med. J.* 1(6110):396-397; 1978.

Because it has been previously suggested that an
body to hepatitis B core antigen (anti-HBc) may
more sensitive indicator of hepatitis B virus re
cation than is hepatitis B surface antigen (HBsA
studies were carried out to determine whether so
patients with HBsAg-negative chronic active hepa-
titis have anti-HBc in their serum and thus have
liver disease that could also be the consequence
hepatitis B virus infection. Anti-HBc was detec
in 26 of 65 patients with HBsAg-negative chronic

ve hepatitis. All of 35 HBsAg-positive patients
anti-HBc. In the 26 anti-HBc-positive, HBsAg-
tive patients, the mean age was 15 yr greater
that in the 35 HBsAg-positive, anti-HBc-positive
ents (p<0.001), and there was a higher percent-
of patients with moderately active liver lesions
.01), a greater prevalence of cirrhosis associ-
with chronic active hepatitis (p<0.05), and a
r mean value for SGPT (p<0.001) in the former
p. The results could indicate that the liver
ase in the HBsAg-negative patients is the con-
ence of chronic infection with hepatitis B vi-
or that the two groups represent either two
es of chronic infection with hepatitis B virus
wo types of response to it.

4 CHRONIC ACTIVE HEPATITIS, HAEMOLYTIC
ANAEMIA AND Listeria monocytogenes BAC-
EMIA. (Eng.) Chadwick, R. G.; Graham, J. M.
al Free Hosp., Pond St., London NW3 2QG,
land). *Postgrad. Med. J.* 54(627):55-57; 1978.

case of a patient with transient *Listeria*
cytogenes bacteremia and hemolytic anemia
ciated with chronic active hepatitis is pre-
ed. The patient, a 53-yr-old woman, presented
a 3-week history of jaundice, dark urine,
pale feces. She had been breathless on exer-
and tired for 1 week. The patient was treated
prednisolone (30 mg, reducing to 20 mg/day)
17 months. The hemolytic anemia responded com-
ely, and the serum proteins and liver function
s returned to normal. Eight weeks after pred-
lone was stopped, the patient presented with a
ay history of worsening obstructive jaundice,
exia, night sweats, and fever. A liver biopsy
ed established cirrhosis. Blood cultures pro-
d a growth of *L. monocytogenes* type 1/2, but
he time the organism had been isolated the
fever had settled without antibiotics, and repeat blood cultures were negative. This patient appears to be exceptional in having recovered spontaneously from this type of bacteremia.

6445 HYPERVISCOSITY SYNDROME ATTRIBUTABLE TO HYPERGLOBULINEMIA IN CHRONIC ACTIVE HEPATITIS. (Eng.) Lee, W. M.; Lebwohl, O.; Chien, S. (161 Fort Washington Ave., New York, NY 10032). *Gastroenterology* 74(5, Part 1):918-921; 1978.

The case of an 18-yr-old woman with clinical and histological features of chronic active hepatitis who was noted to have extremely high levels of immunoglobulin (14.6 g/dl) is presented. The hyperglobulinemia was associated with the hyperviscosity syndrome, diffuse coagulation abnormalities, and renal insufficiency in the absence of severe liver disease. Correction of these features occurred with plasmapheresis before corticosteroid therapy was begun. A similar group of persons with very high γ-globulin levels, described previously under the heading of "plasma cell hepatitis," may form a distinct and rare subgroup of chronic active hepatitis patients.

6446 LYMPHOCYTE SUBPOPULATIONS IN CHRONIC LIVER DISEASE. (Eng.) McFarlane, I. G.; Eddleston, A. L. W. F.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *Clin. Exp. Immunol.* 30(1):1-3; 1977.

See also, 6351, 6353, 6358, 6362, 6370, 6383, 6406,

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7 LIVER SIZE AND INDICES OF DRUG METABOLISM
IN ALCOHOLICS. (Eng.) Pirttiaho, H. I.;
aniemi, E. A.; Ahlqvist, J.; Pitkanen, U.; Pel-
en, R. O. (Dept. Internal Medicine, Univ. Oulu,
90220 Oulu 22, Finland). *Eur. J. Clin. Pharmacol.*
1):61-67; 1978.

role of liver size in drug metabolism was inves-
ated in 34 chronic alcoholics and 28 controls by
paring antipyrine half-life with biopsy content,
al amount of hepatic cytochrome P-450 (P-450),
liver weight. Liver weight was significantly
ater in alcoholics than in controls in terms of
h absolute liver weight (g; p<0.001 in cir-
sis and alcoholic hepatitis, p<0.005 in fatty liv-
) and in terms of relative weight (g/kg; p<0.001
cirrhosis, p<0.005 in alcoholic hepatitis, p<0.01
in fatty liver). Alcoholics with normal histology also had heavier livers (p<0.005). Total P-450 was increased and antipyrine half-life was enhanced in alcoholics with normal liver histology (28.11×10^3 nmol and 6.7 hr, resp., p<0.05 in both cases). In subjects with alcoholic hepatitis or cirrhosis, the antipyrine half-life was prolonged (p<0.001) and P-450 was decreased (p<0.01 and p<0.05, resp., for hepatitis and cirrhosis; p<0.001 in both cases when P-450 was expressed as nmol/g). Alcoholics with fatty liver had a reduced P-450 content, but the total amount of P-450 and the antipyrine half-life were normal. The results demonstrate, in alcoholics, that an enlarged liver of normal histological appearance is associated with enhanced drug metabolism. In subjects with fatty liver, the drug metabolizing capacity per unit weight of liver is

often impaired, but the increase in liver size leads to undisturbed total oxidizing capacity and normal *in vivo* metabolism. In alcoholic hepatitis, drug metabolism is impaired in spite of hepatomegaly. In cirrhosis, the enlargement of the liver appears to compensate for the decreased P-450 content, resulting in only slightly decreased total P-450, and the severely impaired *in vivo* drug metabolism may be due to derangement of blood flow.

6448 INFLUENCE OF STEROIDS ON UREA-CYCLE ENZYMES IN CHRONIC HUMAN LIVER DISEASE.

(Eng.) Maier, K. P.; Talke, H.; Heimsoeth, H.; Gerok, W. (Medizinische Universitats-Klinik, Hugstetter Str. 55, D-7800 Freiburg, W. Germany). *Klin. Wochenschr.* 56(6):291-295; 1978.

To determine the effects of steroids on urea cycle enzymes in liver disease, the activities of Krebs-Henseleit enzymes were determined in liver biopsies of normal controls and of patients with alcoholic hepatitis and chronic active hepatitis after prednisone administration. Prednisone was administered for 5 days in decreasing doses (1.5 mg-0.5 mg/kg) to both patients with alcoholic hepatitis and controls. Patients with chronic active hepatitis received 15-20 mg prednisone daily for more than 3 months. In controls prednisone did not influence the activities of Krebs-Henseleit enzymes. In patients with alcoholic hepatitis, most of the urea-cycle enzymes were significantly decreased in activity ($p<0.05$) before treatment when compared with those in controls. After glucocorticoid administration, the enzyme activities remained unchanged. The activities of most of the urea cycle enzymes were significantly ($p<0.05$) decreased in untreated patients with chronic active hepatitis. In some patients, glucocorticoid administration was associated with clinical, biochemical, and histological remission. The activities of the rate-limiting enzymes of the urea cycle, arginosuccinate synthetase and carbamylphosphate synthetase, increased significantly ($p<0.05$) in these patients. By contrast, alterations of enzyme activities were not observed in patients who failed to respond favorably to steroid treatment. The increase in most urea cycle enzymes in patients with successfully treated chronic active hepatitis would indicate a restored capacity of the liver to synthesize urea.

6449 PATHOGENESIS AND EARLY DIAGNOSIS OF ALCOHOLIC LIVER INJURY.

(Eng.) Lieber, C. S. (Veterans Admin. Hosp., Bronx, NY). *N. Engl. J. Med.* 298(16):888-893; 1978.

The pathogenesis of alcoholic liver injury and its early detection are discussed. Experiments with baboons have indicated that cirrhosis can develop after high alcohol consumption even when the diet is adequate, suggesting that alcohol itself, rather than the malnutrition associated with alcoholism, is a cause of liver injury. A test comparing the level of alpha-amino-n-butyric acid, which is elevated in the plasma of alcoholics, to that of leucine and concurrently measuring γ-glutamyltranspeptidase has been useful in detecting active alcoholism. Liver injury occurs and progresses because of the deleterious effects of intracellular protein accumulation, elevated blood acetaldehyde levels, microsomal activation of hepatotoxins, alterations in redox state, and lymphocyte cytotoxicity. The activity of serum glutamic dehydrogenase correlates much better with the degree of liver necrosis and inflammation than does the activity o serum transaminases or γ-glutamyltranspeptidase, probably because of its much higher content in the liver and its selective localization. The presenc of pericentral sclerosis at the fatty liver stage is an indication that the patient is likely to develop cirrhosis. Changes in collagen metabolism also appear to be important in the development of cirrhosis, and agents that interfere with collagen production or secretion may prove to be helpful in alcoholic patients.

6450 ACUTE CHOLESTASIS, HEPATIC FAILURE, AND FATTY LIVER IN THE ALCOHOLIC.

(Eng.) Morgan, M. Y.; Sherlock, S.; Scheuer, P. J. (Royal Free Hosp., Pond St., Hampstead, London, England). *Scand. J. Gastroenterol.* 13(3):299-303; 1978.

Case reports are presented for three alcoholics, of whom died, who presented with acute cholestasi and hepatic failure and who showed predominantly fatty change on liver biopsy. Each patient had drunk 100-375 g ethanol/day for 12-20 yr. All ha neglected their diet for 6 months prior to admission. Liver tests showed values of >50 μM for serum bilirubin, suggesting cholestasis, and at least 30 King-Armstrong U/dl for serum alkaline phosphatase activity; aspartate transaminase valu were elevated, indicating hepatocellular damage. Presenting symptoms such as malaise, anorexia, hepatomegaly, leukocytosis, and cholestasis indicated that the patients were suffering from acu alcoholic hepatitis, however, the classical histological elements of this disease such as centrilobular liver cell swelling, Mallory bodies, foca infiltration by neutrophils, and pericellular fibrosis were not observed. Histological features (at biopsy or autopsy) were similar in all three patients. There was severe fatty change with cholestasis; many centrizonal liver cells contained fine vacuoles in addition to larger fat droplets; portal tracts were enlarged and contained inflammatory cells and proliferated bile ducts; fibrosi extended from the portal tracts into the lobules a variable extent.

6451 VITAMIN-A REVERSAL OF ABNORMAL DARK ADA TATION IN CIRRHOSIS: STUDY OF EFFECTS THE PLASMA RETINOL TRANSPORT SYSTEM.

(Eng.) Russell, R. M.; Morrison, S. A.; Smith, F. R.; Oaks, V.; Carney, E. A. (Veterans Admin. Hosp., 3900 Lo Raven Blvd., Baltimore, MD 21218). *Ann. Intern. Med.* 88(5):622-626; 1978.

Studies were carried out to investigate to what e tent abnormalities of dark adaptation are associated with abnormalities in plasma retinol transpo and whether the supplemental vitamin A-associated reversal of dark adaptation abnormalities is medi

by its effects on the plasma retinol transport
tem. Of 26 patients hospitalized with mild to
erate alcohol-associated cirrhosis, 14 had dark-
ptation abnormalities consistent with marginal
amin A status. The response of dark adaptation
the plasma retinol transport proteins, retinol-
ding protein and prealbumin, was studied in 12
these patients after daily p.o. vitamin A supple-
ts (3,300 μg/day). Vitamin A supplementation
associated with significant ($p<0.05$-0.005) im-
vement in dark adaptation and increased plasma
centrations of retinyl esters ($p<0.005$), retinol
0.005), and retinol-binding protein ($p<0.05$).
s, in patients with cirrhosis and marginal vita-
A status, supplemental vitamin A therapy appears
stimulate retinol-binding protein release from
liver. This enhancement of plasma retinol trans-
t and delivery of retinol to peripheral tissues
h as the retina is one of several factors that
serve to optimize vitamin A nutritional status
patients with cirrhosis.

2 EFFECTIVE 25-HYDROXYLATION OF VITAMIN
D_2 IN ALCOHOLIC CIRRHOSIS. (Eng.)
ner, D. B.; Russell, R. M.; Absood, S.; Connor,
3.; Davis, C.; Martin, L.; *et al.* (Veterans
in. Hosp., 3900 Loch Raven Blvd., Baltimore,
21218). *Gastroenterology* 74(5, Part 1):866-
; 1978.

ause metabolic bone disease is commonly seen
alcoholism and cirrhosis, the prevalence of
serum 25-hydroxy vitamin D (25-OH-D) levels
reduced bone density were studied in severe,
ole alcoholic cirrhosis. Studies were carried
to determine whether any correlation exists
ween low serum 25-OH-D levels and reduced bone
eral content as measured by bone density of the
tal radius. The responses of serum 25-OH-D,
cium, phosphorus, serum immunoreactive para-
roid hormone (IPTH), and bone density to long
n vitamin D_2 treatment were also investigated.
rty-two patients were studied, and low serum
OH-D was found in 14. Among 23 of the 32,
mean bone density of the distal radius was
ow that of normal age and sex-matched Baltimore
, although the reduction in bone density did
correlate with serum levels of 25-OH-D. Thir-
n patients with low serum 25-OH-D levels (i.e.,
ng/ml) were treated with p.o. vitamin D_2,
ch raised their serum 25-OH-D from a mean base-
e value of 7 ± 1 ng/ml to 116 ± 1 ng/ml within
onth. Normal or supranormal levels of 25-OH-D
n persisted throughout the 3- to 6-month treat-
t period. Mean bone density fell after 3
ths of treatment ($p<0.01$), but in those who
pleted 6 months, it rose back to pretreatment
els. During vitamin D therapy, serum calcium
e ($p<0.05$), and serum phosphorus fell ($p<0.05$).
n serum parathyroid hormone levels did not
nge significantly at any time during treatment.
s study demonstrates that patients with severe,
anced alcoholic cirrhosis are capable of forming
OH-D in amounts sufficient to result in meta-
ic activity in bone. Low serum levels of 25-
D in alcoholic cirrhotics cannot be explained
y by defective 25-hydroxylation of vitamin D.

6453 NONALCOHOLIC FATTY LIVER WITH ALCOHOLIC HYALIN AFTER LONG-TERM GLUCOCORTICOID THERAPY. (Eng.) Itoh, S.; Igarashi, M.; Tsukada, Y.; Ichinoe, A. (Chiba Univ. Sch. Medicine, 1-8-1 Inohana, Chiba, Japan). *Acta Hepatogastroenterol. (Stuttg.)* 24(6):415-418; 1977.

The case of a 34-yr-old nonalcoholic woman in whom alcoholic hyalin was found in the liver after long-term glucocorticoid therapy for systemic lupus erythematosus is presented. Hepatocytes including hyalin bodies showed fatty change or vesiculated degeneration. Occasionally, a basophilic substance, which was recognized in the hepatocytes with or without hyalin, was noticed showing features similar to delicate alcoholic hyalin. Alcoholic hyalin occurring in a case of fatty liver following glucocorticoid therapy has not been previously described.

6454 ALCOHOLIC HEPATITIS. (Eng.) Sabesin, S. M.; Hawkins, H. L.; Bertram, P. D.; Mann, J. A.; Peace, R. J. (Univ. Tennessee Center for Health Sciences, 951 Court Ave., Memphis, TN 38163). *Gastroenterology* 74(2):276-286; 1978.

Three case histories are presented to illustrate various clinical and pathological manifestations of acute alcoholic hepatitis, and other aspects of the disease are reviewed. A 32-yr-old man, who was hospitalized four times during a 3.5-yr period and continued to drink heavily between hospitalizations, developed in succession biopsy-proven fatty liver, alcoholic hepatitis, cirrhosis, and hepatocellular necrosis and died from aspiration during an upper gastrointestinal hemorrhage. A 31-yr-old woman was hospitalized with a 3-week history of heavy alcohol consumption and a history of chronic alcoholism. Three complications occurred: daily fever for 1 month, attributed to ongoing hepatocellular necrosis; marked sustained hyperbilirubinemia associated with elevated alkaline phosphatase; and ascites and minimal hypertransaminasemia. This case demonstrates that intense and prolonged cholestasis may occur in acute alcoholic hepatitis and may simulate extrahepatic biliary obstruction. A 40-yr-old man with both chronic and acute alcoholic liver disease died from fulminant hepatic failure on the 7th day of hospitalization. Alcoholic hepatitis and its progression to cirrhosis may be mediated by immune mechanisms. It has been proposed that once hepatotoxicity has been initiated, injury may be perpetuated by the cytotoxic lymphokines elaborated by T-lymphocytes after exposure to alcoholic hyaline or acetaldehyde. Patients with alcoholic hepatitis have characteristic abnormalities in plasma lipoprotein electrophoretic patterns. Severe alcoholic hepatitis with encephalopathy may be helped by high doses of corticosteroids and drugs that inhibit collagen biosynthesis or secretion may help prevent cirrhosis.

6455 DEPRESSED DELAYED CUTANEOUS HYPERSENSITIVITY IN ALCOHOLIC HEPATITIS. (Eng.) Snyder, N.; Bessoff, J.; Dwyer, J. M.; Conn, H.

O. (Univ. Texas Medical Branch, Galveston, TX 77550). *Am. J. Dig. Dis.* 23(4):353-358; 1978.

Because a negative response to intermediate purified protein derivative (PPD) antigen has been observed in alcoholic hepatitis, delayed cutaneous hypersensitivity was studied in 10 patients with severe alcoholic hepatitis, 9 patients with either inactive alcoholic cirrhosis or alcoholic fatty liver, and 10 age-matched controls. The mean response of the alcoholic hepatitis group was significantly less compared with controls for streptokinase-streptodronase (SK-SD, $p<0.001$), mumps ($p<0.001$), trichophyton ($p<0.025$), and *Candida albicans* ($p<0.025$) antigens. Upon clinical recovery, the response of the six surviving patients with alcoholic hepatitis was similar to controls for four of the five antigens tested, and the improvements in response to SK-SD and *Candida albicans* were significant ($p<0.02$ and $p<0.05$, resp.). The mean percentage and absolute numbers of thymus-derived lymphocytes were significantly less in the alcoholic hepatitis group compared with controls ($p<0.05$ and $p<0.025$, resp.). Both the alcoholic hepatitis patients and patients with less advanced alcoholic liver disease had a diminished response to concanavalin A and phytohemagglutinin. This study demonstrates a reversible depression of delayed cutaneous hypersensitivity in alcoholic hepatitis. The authors recommend that skin tests in patients with alcoholic hepatitis be interpreted with this phenomenon in mind.

6456 HEPATIC STEATOSIS IN CHILDREN. (Eng.) Colon, A. R. (Georgetown Univ. Sch. Medicine, Washington, DC). *Am. J. Gastroenterol.* 68(3):260-269; 1977.

Hepatic steatosis in children is reviewed. Childhood hepatic steatosis is a common and generally benign condition that occurs in many pathophysiologic states and is rapidly reversible with correction of the abnormal metabolic state that induced it. The most thoroughly explored pathway of steatosis has been fatty infiltration secondary to ethanol. Another pathway involves decreased apoprotein synthesis. Lipolysis of adipose tissue triglyceride or hydrolysis of lipoprotein and chylomicron triglyceride by extrahepatic lipases can result in hepatic fatty infiltration as can abnormal hormonal states and various nutritional deficiencies. Childhood hepatic steatosis has a variety of causes, including toxic, nutritional, metabolic, inflammatory, and storage factors. Tox causes include aflatoxin, amanitatoxin, ethanol, and poisoning with carbon tetrachloride, arsenic, lead, diethylene glycol, phosphorus, chloroform, and vitamin A. Intestinal by-pass procedures, cystic fibrosis, and kwashiorkor can all produce steatosis as can several nutritional deficiencies. Metabolic causes include galactosemia, the glycogenoses, hyperlipoproteinemia, and several familia metabolic syndromes. Among the inflammatory cause are chronic bowel diseases, and sepsis. Storage abnormalities implicated in steatosis include α-1-antitrypsin deficiency, histiocytosis, and the gangliosidoses. Treatment involves the removal of the responsible toxin, bacterium, or drug, dietary control, or nutritional replacement therapy.

6457 ALCOHOLIC HEPATITIS WITH AND WITHOUT ALCOHOLIC HYALINE. (Eng.) Nakamura, S.; Takezawa, Y.; Sato, T.; Aikawa, T.; Kera, K. (Tohoku Univ. Health Center, Sendai 980, Japan). *Tohoku J. Exp. Med.* 123(4):351-358; 1977.

6458 CONTINUOUS LOW DOSE PERIPHERAL VEIN PITRESSIN INFUSION IN THE CONTROL OF VARICEAL BLEEDING. (Eng.) Rigberg, L. A.; Ufberg, M. H.; Brooks, C. M. (Memorial Hosp., Phoenix, AZ). *Am. J. Gastroenterol.* 68(5):481-484; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

6459 ALVEOLAR-CAPILLARY OXYGEN DISEQUILIBRIUM IN HEPATIC CIRRHOSIS. (Eng.) Davis, H. H., II; Schwartz, D. J.; Lefrak, S. S.; Susman, N.; Schainker, B. A. (Jewish Hosp. of St. Louis, 216 S. Kingshighway, St. Louis, MO 63110). *Chest* 73 (4):507-511; 1978.

Physiological and pathologic studies were carried out in a 35-yr-old man with cyanosis, clubbing, and cirrhosis to investigate the mechanism for the hypoxemia observed frequently in severe hepatic disease. Pulmonary function was normal except fo a low diffusing capacity and a 28% shunt while th patient was breathing 100% oxygen. A perfusion scan with radioactive ^{99m}technetium-labeled macro aggregated albumin revealed 67% of the labeled macroaggregated albumin in the systemic circulati Postmortem examination demonstrated normal pulmon parenchyma, markedly dilated intraparenchymal cap illaries and arterioles, subpleural angiomata, an

rhosis. No anatomic arteriovenous connections
e demonstrated before or after death. It is
cluded that the arterial hypoxemia of some pa-
nts with hepatic cirrhosis results from dilated
-exchanging blood vessels. These widened ves-
s prevent end pulmonary capillary oxygen tension
m reaching equilibrium with alveolar gas, per-
s because of the widened distance for diffusion.

) ABNORMAL LIPOPROTEINS IN A CASE OF PRIMARY
BILIARY CIRRHOSIS. (Eng.) Etienne, J.;
ler, I.; Ayrault, M.; Cloarec, M.; Polonovski,
Debray, J. (Laboratoire de Biochimie et Clin-
medicale A, CHU Saint-Antoine, Paris, France).
edicine [*Express*] 29(1):33-37; 1978.

serum lipoproteins of a patient with primary
ary cirrhosis were studied during the various
utive stages of the disease. During the pre-
ric period, the serum lipoprotein had the chem-
composition of that found in cholestasis (rich
holesterol and phospholipids); however, the serum
rubin level was normal, and no lipoprotein X
) was detected; there was a normal esterified
otal cholesterol ratio and the α lipoprotein
not decreased, as expected, but increased and
divided into two fractions; immunoelectrophor-
studies of ultracentrifugal fractions showed
lipoprotein with high-density lipoprotein
) immunological properties, but with lower
ities than those of normal HDL. The authors
est that the phospholipid overloading of some
hese HDL in the patient's serum could explain
changes in density. During the icteric period,
patient's serum exhibited characteristics
holestasis, with disappearance of HDL and the
arance of LPX. During the subsequent period,
serum again contained phospholipid rich HDL and
Several LPX with different densities were
d. It seems that, in cholestasis, lipoproteins
rgo modification in which the HDL peptide chains
an important role.

FAMILIAL CLUSTERING AND IMMUNE RESPONSE IN
FAMILY CONTACTS OF PATIENTS WITH HBsAg-
TIVE LIVER CIRRHOSIS. (Eng.) Eliakim, M.;
mski, M.; Sandler, S. G.; Zlotnick, A. (Hadassah
. Hosp., P.O. Box 499, Jerusalem, Israel). *Am.*
ig. Dis. 23(5):407-412; 1978.

lies of 11 patients with hepatitis B surface
gen (HBsAg)-positive cirrhosis were studied to
uate the immunologic correlates and extent of
afamilial HBsAg clustering. Of 76 family con-
s, 12 were identified to be asymptomatic car-
s of HBsAg and 2 were diagnosed as having HBsAg-
tive cirrhosis. The overall HBsAg prevalence
the 76 contacts was 18% and that for all 87
ers studied was 29.0%. Serologic evidence of
titis B virus (HBV) infection (either HBsAg, anti-
or both) was detected in 59% of all family
ers. HBsAg was more prevalent in men (47%) com-
d with women (16%), whereas antibody to HBs
i-HBs) was more prevalent in women (42%) com-
d with men (18%). Evidence of an immunologic
onse in clinically unaffected HBsAg-negative
family contacts consisted of elevated serum IgG levels (mean 1,660 mg/100 ml) and increased prevalence of antismooth muscle and antimitochondrial antibodies (16% and 6%, resp.). The prevalence of one or more autoantibodies in all HBsAg-negative family contacts was 20%, and it was higher in women (25%) than in men (13%). This study demonstrates that HBsAg clustering occurs in families of cirrhotic patients in the Jerusalem area and indicates that HBsAg-negative family contacts may have increased B-cell activity.

6462 ELECTRONEUROGRAPHIC EVIDENCE OF POLYNEUROPATHY IN CHRONIC LIVER DISEASE. (Eng.) Vasilescu, C.; Florescu, A.; Balta, N. (Inst. Neurology and Psychiatry, Sos. Berceni 10--12, C.P. 5880, R-75622 Bucharest, Rumania). *Arch. Psychiatr. Nervenkr.* 225(1):87-96; 1978.

An electroneurographic study of the peripheral nerves was carried out in 25 patients with severe cirrhosis following viral hepatitis to determine whether this type of study would be of value in the early diagnosis of peripheral neuropathy in cirrhosis. There was a slight slowing ($p>0.05$) of motor conduction velocity (CV) and a significant diminution ($p<0.001$) of sensory CV and mixed sensorimotor-evoked potentials, associated with a significant decrease in the amplitude of sensory evoked potentials. The slowing was about equal in the distal (digital) and in the proximal segments of the same nerve. A mixed axonal degeneration and segmental demyelination may explain these findings. The CV measurements proved helpful for an early diagnosis of hepatic polyneuropathy showing subjective symptoms in the subclinical stage.

6463 SPECTRUM OF RENAL TUBULAR DAMAGE IN RENAL FAILURE SECONDARY TO CIRRHOSIS AND FULMINANT HEPATIC FAILURE. (Eng.) Wilkinson, S. P.; Hirst, D.; Day, D. W.; Williams, R. (King's Coll. Hosp. and Medical Sch., London SE5, England). *J. Clin. Pathol.* 31(2):101-107; 1978.

Measurements of urinary lysozyme were used to evaluate renal tubular integrity in 34 patients with cirrhosis or fulminant hepatic failure who had developed renal impairment, and the results were compared with the histological findings and the laboratory tests usually used in the differentiation of functional renal failure from acute tubular necrosis. In 18 of the patients, the lysozyme fractional clearance values were normal (<1%) but in the remaining 16 were increased (ranging up to 78%), supporting previous concepts that renal failure complicating hepatocellular disease may occur both without and with tubular necrosis. The lysozyme values were inversely related to the creatinine clearance (14/15 patients with creatinine/clearance of ≥3 ml/ml had normal lysozyme values, whereas 15/19 with creatinine clearance of <3 ml/min had elevated lysozyme values), suggesting that the development of tubular necrosis may be determined by the level of renal perfusion. The validity of simpler laboratory tests often used to assess renal tubular integrity--namely, the urine sodium concentration, the urine:plasma osmolality ratio, and casts in the urine sediment--was evaluated by comparison with the lysozyme measurements. The urine sodium concentration was of most value (patients with normal lysozyme levels always had <12 mM Na in the urine, but patients with elevated lysozyme levels (with one exception) always had high Na levels, with a maximum of 110 mM) and the findings in the sediment were of no value at all.

6464 RHEUMATIC DISORDERS IN PRIMARY BILIARY CIRRHOSIS. (Eng.) Clarke, A. K.; Galbraith, R. M.; Hamilton, E. B. D.; Williams, R. (Royal Natl. Hosp. Rheumatic Diseases, Upper Borough Walls, Bath BA1 1RL, England). *Ann. Rheum. Dis.* 37(1):42-47; 1978.

Eighty-three patients with primary biliary cirrhosis were investigated to determine the prevalence of rheumatic disorders. Fourteen patients had scleroderma, which tended to be mild, but in several patients it produced severe systemic manifestations. Keratoconjunctivitis sicca occurred in all but one of the patients with scleroderma. The CRST syndrome (calcinosis, Raynaud's phenomenon, sclerodactyly, telangiectasia) was only identified twice. There was an increased incidence of histocompatibility locus antigens A1+B8 in those patients with scleroderma (10/14), compared with that in 89 healthy controls (17%, $p<0.01$). In addition to those with scleroderma, four patients had a destructive arthropathy resembling avascular necrosis. Four patients had an inflammatory arthritis, without specific features, but the frequency was no greater than might be expected in the general population. Both keratoconjunctivitis sicca and scleroderma complicating biliary cirrhosis may be due to an immune response.

6465 INCORPORATION OF RADIOCOPPER INTO CERULOPLASMIN IN NORMAL SUBJECTS AND IN PATIENTS WITH PRIMARY BILIARY CIRRHOSIS AND WILSON'S DISEASE. (Eng.) Vierling, J. M.; Schrager, R.; Rumble, W. F.; Aamodt, R.; Berman, M. D.; Jones, E. A. (Liver Unit, Building 10, Room 4D-52, NIH, Bethesda, MD 20014). *Gastroenterology* 74(4):652-660; 1978.

To investigate whether measurements of the incorporation of radiocopper into ceruloplasmin are of value in distinguishing between different diseases associated with accumulation of copper in the tissues, the kinetics of the incorporation of i.v. or p.o. administered radiocopper into ceruloplasmin were studied in eight normal subjects and in eight patients with hepatic copper overload states (6 with primary biliary cirrhosis and 2 with Wilson's disease). After 0.8 days, the radiocopper content of ceruloplasmin in serum was negligible in the patients with Wilson's disease, whereas it was appreciable in the remaining subjects. Total incorporation of radiocopper into ceruloplasmin was calculated by deconvoluting plasma curves of radiocopper in ceruloplasmin with the plasma disappearance curve of i.v. administered radioiodinated
ceruloplasmin, and integrating the derived functi
In normal subjects, incorporation of radiocopper
into ceruloplasmin was reduced by approximately 5
when the isotope was given p.o. rather than i.v.
Plots of the curves of total incorporation of rad
copper into ceruloplasmin against time revealed
components that were approximately linear betwee
2 and 7 days. Extrapolation of these components
to zero time yielded positive intercepts with the
ordinate, which were relatively smaller in the
patients with primary biliary cirrhosis than in
the normal subjects. It is concluded that: (1)
measurements of incorporation of radiocopper int
ceruloplasmin can be used to distinguish between
two hepatic copper overload states; (2) approximately 50% of p.o. administered radiocopper is n
absorbed; (3) copper is incorporated into ceruloplasmin by at least two different pathways, a
slower route that probably involves initial equi
ibration with a hepatic storage pool, and a more
rapid route that presumably bypasses this pool;
and (4) incorporation of radiocopper into ceruloplasmin via the more rapid pathway is impaired i
primary biliary cirrhosis.

6466 NEOMYCIN-SORBITOL AND LACTULOSE IN THE
TREATMENT OF ACUTE PORTAL-SYSTEMIC ENCEPHALOPATHY: A CONTROLLED, DOUBLE-BLIND CLINIC
TRIAL. (Eng.) Atterbury, C. E.; Maddrey, W. C.
Conn, H. O. (Veterans Admin. Hosp., West Spring
West Haven, CT 06516). *Am. J. Dig. Dis.* 23(5):3
406; 1978.

In a double-blind, randomized study, the efficac
of lactulose was compared with that of Neomycin-
bitol in the treatment of 45 episodes of acute
genous portal systemic encephalopathy (PSE) ind
by dietary protein, azotemia, or gastrointestin
hemorrhage. All 35 patients had underlying cirrhosis and, at the time of randomization, had e
cephalopathy of at least grade 2 severity and a
terial ammonia concentrations greater than 150
100 ml. Two-thirds of the patients in each gro
returned to normal mental status, and more than
in each group showed an improvement of at least
grade in mental state. In addition, there was
equivalent improvement in asterixis, in the per
ance of the Number Connection Test, in the elec
encephalographic pattern, and in arterial ammon
concentration. The principal difference betwee
the two groups was a greater reduction in stool
after lactulose therapy (from 7.0 to 5.5 after
apy, $p<0.001$) than after neomycin-sorbitol ther
(from 7.0 to 6.5, $p<0.01$). One patient random
to neomycin-sorbitol had to be withdrawn from t
study because of persistent vomiting related to
administration of the medication. Otherwise, t
were no complications attributable to therapy i
either group. These data suggest that neomycin-
sorbitol and lactulose are equally effective in
treatment of acute nitrogenous portal systemic
cephalopathy.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

59 EFFECT OF IOGLYCAMIDE (BILIGRAM) ON BILE FLOW AND BILIARY LIPID SECRETION IN MAN.
g.) Bell, G. D.; Doran, J.; Fayadh, M.; Murphy,
Dowling, R. H. (City Hosp., Nottingham, England).
: 19(4):300-307; 1978.

e effect of ioglycamide on bile flow and biliary
id output was studied in man. Twenty-one anic-
ic patients with a t-tube *in situ* were studied
ween the 9th and 11th postoperative days; 11
ients were given an i.v. infusion of ioglycamide
mg/kg/min for 2 hr in 5 patients and 4 mg/kg/min
1 hr plus 1 mg/kg/min for 30 min in 6 patients),
the other 10 acted as controls. Bile flow
recorded, and the biliary concentrations of
lycamide, bile salt, phospholipid, and choles-
ol were estimated in the two groups. The bili-
excretion of ioglycamide was associated with
ignificant choleresis ($p<0.001$ or $p<0.01$), which
probably due to the obligatory coupling of the
otically active contrast agent molecules with
er. Biliary ioglycamide excretion did not sig-
icantly alter bile salt secretion rates. In
trast, the biliary secretion of both phospho-
id and cholesterol was significantly lowered
0.001). Unlike chenodeoxycholic acid, ioglyca-
e significantly reduced bile acid independent
lesterol secretion ($p<0.01$), although secretion
e in terms of micromoles of cholesterol per
romoles of bile acid was essentially unchanged.
se studies show that the biliary excretion of
lycamide is associated with a significant chole-
is that is independent of bile salt secretion.
authors conclude that ioglycamide might prove
be a prototype for the future development of an
lly-administered drug for dissolving cholesterol
lstones.

0 VALUE OF THE CHIBA NEEDLE IN THE TECHNIQUE OF PERCUTANEOUS TRANSHEPATIC CHOLANGIO-
PHY: A REPORT OF 20 CASES. (Fre.) Grenier, P.;
ault, M. J.; Brault, B.; Nahum, H. (Hopital Beau-
, 100, boulevard du General Leclerc, F 92110
chy, France). *J. Radiol. Electrol. Med. Nucl.*
10):659-663; 1977.

Chiba needle, much finer and more flexible than
ventional ones, was used for percutaneous transhepatic cholangiography in 20 patients with cholestasis. Opacification of the biliary canals was possible in 15/16 patients with dilated bile ducts and in 4/4 patients with undilated ducts. In seven cases, incomplete opacification occurred, especially of canals on the left side (the puncture usually centers on the right side of the liver); the gallbladder was badly opacified in seven cases and there was no duodenal passage in four cases. It appears more difficult to aspirate bile during this procedure than with the use of larger diameter needles, which accounts for the problems of opacification. There were nine intraparenchymatous injections (which interfered with the examination twice), four subcapsular injections, and a periportal injection which necessitated interruption of the procedure. No infectious complications occurred (the risk of biliary peritonitis is only 0.64%). Surgery is not imperative after this technique and may be deferred if necessary. The success in catheterizing undilated biliary canals makes this a valuable procedure in cases of prolonged hepatitis or anicteric cholestasis.

6471 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY AND NEEDLE BIOPSY IN THE DIFFERENTIAL DIAGNOSIS OF OBSTRUCTION OF BILE FLOW. (Eng.) Wessely, Z.; Chawla, S. K.; Klavins, J. V. (Queens Hosp. Center, 82-68 164th St., Jamaica, NY 11432). *Am. J. Gastroenterol.* 68(6):582-594; 1977.

Twenty-four patients with clinical evidence of obstructive jaundice were examined by percutaneous transhepatic cholangiography (PTC) and needle biopsy (NB) of the liver to evaluate the combined application of these techniques in the diagnosis of liver diseases. The presence of extrahepatic bile duct obstruction was confirmed by surgery in 21 cases. PTC and the combination of both methods were superior to NB alone in the differential diagnosis between extra- and intra-hepatic biliary obstruction. Sampling bias added to the difficulties of NB in distinguishing between these two types of obstruction. The combination of both procedures proved most useful in three cases with intrahepatic obstruction, in which the patients were spared unnecessary surgery. In five cases, the NB provided additional information about the nature of the tumor metastases and gave support to the clinicians in their therapeutic approach. A combination of PTC and NB increases diagnostic accuracy markedly, and a negative finding by both techniques should eliminate unnecessary surgery.

6472 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY: EVALUATION BASED ON EXPERIENCE WITH 805 EXAMINATIONS.

(Eng.) Seifert, E. (Staedt Krankenhaus Kemperhof, Koblenzerstr. 115, 5400 Koblenz, W. Germany). *Am. J. Gastroenterol.* 68(6): 542-549; 1977.

Endoscopic retrograde cholangiopancreatography (ERCP) was evaluated on the basis of 805 examinations. Visualization of the common bile duct and the pancreatic duct was possible in 44%, of the common bile duct in 22%, and of the pancreatic duct alone in 24.6% of the cases. The ductal systems were not opacified in 9.4%, but the failure rate decreased from 18.2% to 5.4% within increasing experience. Pathological changes were found in both ducts in 2%, in the common bile duct in 42.2%, and the pancreatic duct in 11.4% of the cases. Diagnostic information was supplied by ERCP in 84.4% of the cases. Complications developed in four cases (acute pancreatitis in 3 and cholangitis in 1). There was no mortality in the entire series. It is concluded that ERCP is a valuable diagnostic method that is frequently successful and reasonably safe.

6473 PERCUTANEOUS TRANSHEPATIC DRAINAGE CATHETER: A VALUABLE THERAPEUTIC AID IN OBSTRUCTIVE JAUNDICE.

(Eng.) Probst, P.; Castenada-Zuniga, W. R.; Amplatz, K. (Univ. Minnesota Hosp., 420 Delaware St. S.E., Minneapolis, MN 55455). *Fortschr. Geb. Rontgenstr. Nuklearmed.* 128(4):443-445; 1978.

The case of a 64-yr-old woman in whom the operative diagnosis of sclerosing cholangitis was made is presented. Following the right nephrectomy and cholecystostomy during which fibrosis, chronic inflammation, and common bile duct tumor were found, bile abscess and intra-abdominal sepsis developed but responded to antibiotics. The patient was discharged but was later readmitted for increasing jaundice; her bilirubin was 11.7 mg/dl. A transhepatic cholangiogram revealed obstruction of the right main bile duct in the porta hepatis. Percutaneous drainage of the biliary system was undertaken; the average daily drainage was 400-700 cm^3. After discharge, the patient was treated by replacement of bile salts and sodium; her bilirubin fell to 6.5 mg/dl after 1 week, to 2.7 mg/dl after 3 weeks, and to normal after 1 month. The transhepatic catheter continued to drain for 3 months, and the cholecystostomy tube began to drain bile as well. A choledochojejunostomy is planned. The main indications for percutaneous decompression of the biliary system are preoperative decompression and primary decompression in patients with obstructive neoplastic disease. The catheter should be advanced under fluorescopic control into one of the major radicles or preferably into the distal common bile duct beyond the point of obstruction.

6474 HEPATO-BILIARY SCINTIGRAPHY AND HEPATOGRAPHY WITH Tc-99m DIETHYL-ACETANILIDO-IMINODIACETATE IN OBSTRUCTIVE JAUNDICE.

(Eng.) Nielsen, S. P.; Trap-Jensen, J.; Lindenberg, J.; Nielsen, L. M. (Frederiksberg Hosp., DK-2000 Copen-
hagen F, Denmark). *J. Nucl. Med.* 19(5):452-457; 1978.

To determine whether serial hepatobiliary scintigraphy can be transformed into a quantitative excretory liver function test and if patients with
significant obstruction of the common bile duct c
be investigated by this method, ^{99m}Tc-diethyl-acetanilido-iminodiacetate (^{99m}Tc-diethyl-IDA) wa
used for combined serial hepatobiliary scintigrap
and processing of hepatographic curves; a scintil
tion camera and an image-processing system were u
in 7 normal subjects and 34 patients with common
bile duct obstruction. In normal fasting subject
and patients with moderate biliary obstruction, t
liver was seen at 1-3 min after i.v. injection, a
reached maximum intensity at 10 min. In patients
with moderately elevated levels of serum bilirubi
and alkaline phosphatase, sufficient anatomical i
formation was obtained by serial hepatobiliary
scintigraphy for 30 min. Complete obstruction wa
diagnosed by the absence of intestinal radioactiv
24 hr after injection. Hepatograms from an area
interest corresponding to the periphery of the ri
liver lobe varied predictably with changes in the
serum levels of alkaline phosphatase and bilirubi
In normal subjects, the time-activity curve in th
area had a maximum of about 10 min. Both anatomi
and functional information was obtained. The investigation could be carried out even under reduc
liver function. Hepatic uptake of the agent was
noted at serum alkaline phosphatase levels up to
1,000 U/1 and serum bilirubin levels up to 170 μ
Although the anatomical information derived from
^{99m}Tc-diethyl-IDA cholescintigraphy is less detailed than that of radiologic methods, this tec
nique can become a valuable diagnostic aid in
cases of obstruction so severe that radiologic c
trast methods are useless or if the patient is
sensitive to contrast media.

6475 SERUM BILE ACIDS AS RELATED TO BILE AC
SECRETION IN LIVER DISEASE.

(Eng.) S
fer, E. A.; Gordon, E. R. (Gastrointestinal Res.
Unit, Univ. Calgary, Calgary T2N 1N4, Alberta, C
ada). *Am. J. Dig. Dis.* 23(5):392-397; 1978.

The level of serum bile acids and their rate of
cretion into the duodenum were measured in norma
subjects and patients with cholesterol gallstone
and hepatobiliary disease to determine if change
in serum bile acids reflect alterations in bile
secretion within the enterohepatic circulation,
pecially in association with disordered bile ac
metabolism and liver dysfunction. To quantitate
bile acid secretion, an intestinal marker perfus
technique was used that measured duodenal outpu
under stimulated but steady-state conditions. I

these perfusion studies, serum bile acids were
rmined at hourly intervals. In the 28 normal
ects, serum bile acids during fasting were low
± 0.7 µM) with only a modest rise occurring
r a fat meal (7.6 ± 0.7 µM). The average bile
secretion rate in these subjects was 1,321
/hr, and little fluctuation was noted in the
m levels (7.5 ± 0.8 µM) during the perfusion
ies. The five patients with cholesterol gall-
es demonstrated a decreased rate of bile acid
etion at 714 µmol/hr ($p<0.05$) but had normal
m values. In 15 gallstone patients who had
rgone cholecystectomy, the bile acid secretion
increased to 1,411 ± 103 µmol/hr without any
esponding change in serum levels. In 19 pa-
ts with liver disease, however, serum bile
s were elevated ($p<0.05$) while bile acid secre-
was reduced ($p<0.05$). Thus, in normal sub-
s, the liver is capable of handling an increased
genous bile acid return with only a small rise
erum levels. In liver disease, bile acid secre-
is reduced while serum concentrations are in-
sed, implying a defect in bile acid handling by
liver. In cholesterol gallstone disease, serum
ls do not reflect the abnormality in bile acid
bolism. The relation between bile acid concen-
ion in the serum and secretion rate into the en-
hepatic circulation is dependent on whether hepa-
dysfunction is present or if bile acid metabolism
bnormal.

BILIARY BILE ACIDS IN UNCOMPLICATED PREGNANCY AND IN CHOLESTASIS OF PREGNANCY.

) Laatikainen, T.; Lehtonen, P.; Hesso, A.
. Central Hosp., Haartmaninkatu 2, SF-00290
nki 29, Finland). *Clin. Chim. Acta* 85(2):
50; 1978.

salt metabolism of conjugated and sulfated bile
was studied in gallbladder bile samples from
pregnant women at term and from two patients
cholestasis of pregnancy by gas-liquid and high-
ure liquid chromatography. In healthy preg-
women, the mean ratio of cholyl/chenodeoxy-
l/deoxycholyl glycine was 3.7:1.0:0.23 and
of the taurine conjugates 3.0:1:0.25, resp.
e gallbladder bile pool of nonpregnant women,
ratios were 1.0:1:0.99 and 1.0:1:0.70, resp.
cholic acid predominated in pregnancy bile.
tients with cholestasis of pregnancy, cholic
comprised 90% of total biliary bile acids,
roportion of chenodeoxycholic acid was greatly
ased, and nonsulfated deoxycholic acid was not
ted. The proportion of sulfated bile acids in
biliary bile acids was between 0.4 and 1.2%
complicated pregnancy and 0.3 and 0.5% in pa-
s with cholestasis. The results suggest that
is a shift to a more extensive biliary ex-
on of taurine as compared to glycine conju-
of bile acids during pregnancy.

LECITHIN-CHOLESTEROL ACYLTRANSFERASE AND THE LIPOPROTEIN ABNORMALITIES OF OBSTRUC-
JAUNDICE. (Eng.) Agorastos, J.; Fox, C.;
, D. S.; McIntyre, N. (Royal Free Hosp., Pond
St., London NW3 2QG, England). *Clin. Sci. Mol. Med.* 54(4):369-379; 1978.

Plasma lipoprotein abnormalities were studied in 16 patients with obstructive jaundice to test the hypothesis that the abnormalities correlate with plasma lecithin-cholesterol acyltransferase activity. Very low-density lipoproteins (VLDL) were normal in composition and had a normal pre-β electrophoretic mobility when lecithin-cholesterol acyltransferase activity was high. When it was low, VLDL had abnormal composition and ran in the β position. With high lecithin-cholesterol acyltransferase activity, low-density lipoprotein (LDL) was normal, and cholestatic LDL (LP-X) was not found. With low lecithin-cholesterol acyltransferase activity, up to three LDL fractions were found: (a) large triglyceride-rich particles, (b) LP-X, and (c) a triglyceride-rich cholesteryl ester-poor particle of normal dimensions. High-density lipoprotein (HDL) concentrations correlated with lecithin-cholesterol acyltransferase activity, and HDL were normal ultrastructurally and in composition when the activity was high. When lecithin-cholesterol acyltransferase activity was low, HDL was abnormal in composition, and "stacked discs," together with normal spherical particles, were seen ultrastructurally. These results suggest that low lecithin-cholesterol acyltransferase activity may cause at least some of the lipoprotein changes of obstructive jaundice.

6478 LYSOSOMAL DEGRADATION OF BILE DEPOSITS IN CHOLESTASIS: AN ULTRASTRUCTURAL AND CYTOCHEMICAL STUDY.

(Eng.) Faria, V. (Medical Sch., Univ. Oporto, Oporto, Portugal). *Virchows Arch. [Cell Pathol.]* 24(4):355-358; 1977.

To elucidate the intracellular fate of hepatocytic bile deposits in cholestasis, liver biopsy specimens obtained at laparotomy from six patients with obstructive jaundice were examined by light and electron microscopy. Membranous and lamellar structures of variable electron density incorporated into vacuoles of different sizes were seen in many hepatocytes. These structures had the characteristic appearances of bile deposits and contained acid phosphatase activity as judged by the deposition of lead phosphate reaction product. The size and intensity of the deposits varied among vacuoles. These results provide additional evidence to support the hypothesis that lysosomes participate in the elimination of retained bile from hepatocytes. It is probable that lysosomal degradation is an important mechanism of intracellular elimination of deposited bile.

6479 CALCIFIED GALLBLADDER (PORCELAIN GALLBLADDER).

(Eng.) Ashur, H.; Siegal, B.; Oland, Y.; Adam, Y. G. (Asaf Harofe Hosp., Tel-Aviv Univ., Zerifin, Israel). *Arch. Surg.* 113(5):594-596; 1978.

The cases of five patients with calcified ("porcelain") gallbladder are presented. The disease appeared mostly in the sixth decade of life (the patients were 62, 61, 41, 75, and 75 yr old) and was more prevalent in women (4/5 patients). The presenting symptoms included abdominal or retrosternal pain in all patients and vomiting or diarrhea in some. Gallbladder calcification was observed by a simple flat plate of the abdomen in four cases, and the remaining case was diagnosed at surgery. Oral cholecystography or i.v. cholangiography showed a nonopacified gallbladder in all cases examined and a narrowed common duct in two. Calcification was associated with gallstones in four cases and with a poorly differentiated adenocarcinoma in the fifth. The findings in these patients and those reported in the literature indicate that surgery should not be delayed even if the patient is asymptomatic, since the occurrence of carcinoma in porcelain gallbladder is remarkably high. The diagnostic work-up should include other roentgenographic examinations in addition to the flat abdominal plate, to exclude calcification of other viscera or the thoracic wall.

6480 THE CLINICAL SIGNIFICANCE OF GALLSTONES AND THEIR RADIOLOGICAL INVESTIGATION.

(Eng.) Earlam, R. J.; Thomas, M. (London Hosp., London, England). *Br. J. Surg.* 65(3):164-167; 1978.

To analyze the clinical symptoms of gallstones and to correlate them with findings from radiological investigations, 122 patients (98 women and 24 men) with gallstones were examined. No specific indigestion was present that could be termed "flatulent dyspepsia." Sensitivity to fatty foods occurred in 69%, heartburn in 42%, regurgitation of acid-tasting or bitter fluid to the mouth in 31%, and increased passage of flatus from the stomach upwards in 38%. If the gallbladder concentrated contrast medium on a p.o. cholecystogram but did not contract after a fatty meal, the patients suffered less heartburn than if the gallbladder functioned normally. The cholecystogram was performed in 111 patients and revealed 60 multiple stones (>10) and 36 solitary stones. However, since surgeons rarely perform a cholecystectomy for flatulent dyspepsia alone, knowledge of gallbladder function may be necessary.

6481 'POLYMER PIGMENTS' IN HUMAN PIGMENT GALLSTONES.

(Eng.) Wosiewitz, U.; Schroebler, S. (Inst. Medical Physics Univ., D-4400 Munster, W. Germany). *Naturwissenschaften* 65(3):162-163; 1978.

To examine whether the black "polymer pigment" in human pigment gallbladder stones is polymerized from bile pigments with a tetra- or with a dipyrrolic structure, gallbladder bile samples obtained by intraoperative puncture from patients who underwent cholecystectomy for pigment cholelithiasis were tested for dipyrrolic compounds by the Stokvis reaction. The black polymer pigment was separated by extraction from the soluble bile pigments, subjected to chromate degradation (oxidation), and analyzed by thin-layer chromatography (TLC). For comparison, biliverdin, urobilin, polymerized propentdyopent, and fecal pigment ("mesobilifuscin") methylesters were also chromate degraded and analyzed by TLC. Bile pigments with a tetrapyrrolic structure (biliverdin and urobilin methylesters) were oxidized to both maleimides and pyrrole dialdehyde The black polymer pigment also gave this pattern. Polymerized propentdyopent and mesobilifuscin methylesters, both polymerized from dipyrrolic monomers, did not yield pyrrole dialdehydes. The results cannot exclude that dipyrrolic polymers are involved in the formation of the black polymer pigment, but it is not composed entirely of such derivatives. It is concluded that the black polymer pigment of human pigment gallstones is based chiefly on the polymerization of tetrapyrrolic bil pigments.

6482 GALLSTONE DISSOLUTION BY CHENODEOXYCHOL ACID AND PHENOBARBITAL.

(Eng.) Marks, W.; Sherman, J. H.; Bonorris, G. G.; Chung, A.; Coyne, M. J.; Schoenfield, L. J. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Box 4870, Los Angeles, CA 90048). *Am. J. Gastroenterol.* 69(2): 160-165; 1978.

Gallstone dissolution and biliary lipids were determined and compared in patients receiving eithe chenodeoxycholic acid (CDC, 28 patients) or CDC and phenobarbital (PB, 20 patients) for 1.5-2 yr, to determine whether PB enhances CDC-induced gall stone dissolution. Among patients with radioluce gallstones, dissolution occurred in 53% of those receiving CDC alone and in only 25% of those receiving both CDC and PB. No dissolution occurre in 13 other patients with calcified gallstones. tients with dissolution had a significantly grea molar percentage of CDC (p<0.02) and a significa lower saturation index in bile than those withou dissolution (p<0.01). Diarrhea and transiently normal liver function tests were the most freque observed side-effects, but only diarrhea necessitated a reduction of the CDC dose. Gallstones r curred following dissolution in one of six patie followed for 6 months after discontinuation of C In conclusion, PB did not enhance either CDC-ind desaturation of bile or gallstone dissolution.

6483 STENOSING ODDITIS: DIAGNOSIS AND TREA REPORT OF 109 CASES.

(Fre.) Lataste, Guegan, Y.; Albou, J. C. (Hopital Intercommunal Creteil, 40, avenue de Verdun, 94 Creteil, Franc *J. Chir. (Paris)* 114(5):317-328; 1977.

A series of 109 patients treated for stenosing ditis represented only 4.5% of all patients wit benign lesions of the extrahepatic bile ducts. Clinical signs were episodes of severe pain (91 icterus (63%), and hyperthermia (41%); these sy toms were of long duration in 74% of the patien Radiologically, the lower choledochus showed a acteristic image of stenosis, but this was ofte obscured by a dilated bile duct. The diagnosis had to be confirmed surgically in 103 patients. Peroperative radiomanometry showed no duodenal sage in 19/76 patients or elevated pressure in 45/76 patients; the pressure was normal 4 times The odditis was almost always accompanied by lithiasis and/or pancreatitis. Treatment was sur

l: sphincterotomies (72) in patients under 50 yr
when there was reflux in a dilated Wirsung's
nal with associated pancreatitis and biliary
rivations (35) in older or weaker patients, es-
cially when the common bile duct was very dil-
ed. Surgical results were good in 84 patients;
ere were 8 instances of minor complications and
of major complications (11 were fatal). Long-
rm results were better and local complications
curred less frequently when biliary derivations
re performed. Since the presence of chronic
ncreatitis did not seem to aggravate the odditis,
hincterotomies should not be performed routinely,
t reserved for young patients with only slightly
lated common bile ducts. For all other patients,
liary derivations should be the treatment of
oice.

6499 INCIDENCE AND SIGNIFICANCE OF DIFFERENT TYPES OF CONNECTIVE TISSUE ANTIBODIES IN ADULT AND PEDIATRIC GASTROENTEROLOGICAL DISORDERS. (Eng.) Rizzetto, M.; Bonino, F.; Pera, A.; Barbera, C.; Santini, B. (Ospedale Mauriziano Umberto I, Cs Turati 46, I-10128 Torino, Italy). *Digestion* 17(1): 29-37; 1978.

To evaluate the clinical relevance of connective tissue antibodies (CTA), they were assessed in sera from 3,000 adult and 388 pediatric patients with gastroenterological disorders involving the stomach, esophagus, and duodenum (31%), liver (52%), colon (8%), pancreas (4.5%), and small bowel (4.5%). A standard fluorescein-conjugated antiserum technique was employed. R_1 antibodies were found in 9 adults with celiac disease (8) and Crohn's disease (1) and in 47 children with celiac disease; malabsorption was a constant feature in patients with R_1 antibodies. Adherent cell antibodies were found in 2 children and 101 adults. These antibodies were not associated with any single clinical entity and occurred in patients with and without malabsorption; however, their incidence was 30% in individuals with steatorrhea but only 3% in those without steatorrhea ($p<0.01$). R_2, KC, and Rs antibodies were observed in adults having unrelated disorders without malabsorption. Although R_2, KC, and Rs antibodies seem to have no clinical significance in gastroenterology, R_1 appears to be related to a malabsorption syndrome and adherent cell antibodies are related to primary and secondary malabsorption.

6500 THE PROTEAN GASTROINTESTINAL MANIFESTATIONS OF METASTATIC BREAST CARCINOMA. (Eng.) Chang, S. F.; Burrell, M. I.; Brand, M. H.; Garsten, J. J. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Radiology* 126(3):611-617; 1978.

Case histories are presented for eight women with breast cancer metastatic to the gastrointestinal tract. Five of the cases were occult, and the patients presented after 7-24 symptom-free yr. In these eight cases, breast cancer metastasized to the esophagus, stomach, colon, uterus, liver, gallbladder, and common bile duct. Some of the cases simulated other diseases, e.g., Crohn's disease or uterine fibroids, which caused difficulty in diagnosis. These findings indicate the importance of being familiar with all the manifestations of metastatic breast cancer and of obtaining a complete medical history.

6501 ANTIBIOTIC-ASSOCIATED DIARRHEA TREATED WITH ORAL TETRACYCLINE. (Eng.) DeJesus, R.; Peternel, W. W. (Mercy Hosp., 1400 Locust St., Pittsburgh, PA 15219). *Gastroenterology* 74(5, Part 1):818-820; 1978.

The cases of three patients with protracted antibiotic-associated diarrhea who did not recover when antibiotics were stopped but had a prompt improvement after tetracycline administration are presented. The patients developed severe, incapacitating diarrhea after antibiotic administration. Presenting features included abdominal discomfort, hematochezia, and hypokalemia from voluminous diarrhea. Roentgenographic studies in one patient were normal, and proctoscopy in two patients failed to show antibiotic-associated colitis. Stool cultures were negative. Despite cessation of antibiotics and symptomatic therapy, the diarrhea continued. After the administration of tetracycli (250 mg, p.o., 4x/day for 1-5 days), the diarrhea stopped without recurrence even after the tetracycline was discontinued. These clinical results suggest that patients with antibiotic-associated diarrhea may benefit from tetracycline when standa medical therapy fails.

6502 PROPHYLACTIC DOXYCYCLINE FOR TRAVELERS' DIARRHEA: RESULTS OF A PROSPECTIVE DOUBLE-BLIND STUDY OF PEACE CORPS VOLUNTEERS IN KENYA. (Eng.) Sack, D. A.; Kaminsky, D. C.; Sack R. B.; Itotia, J. N.; Arthur, R. R.; Kapikian, A. Z.; *et al.* (Baltimore City Hosp., 4940 Eastern Ave., Baltimore, MD 21224). *N. Engl. J. Med.* 298 (14):758-763; 1978.

A randomized double-blind study was carried out to determine the efficacy of doxycycline (100 mg/day) in preventing travelers' diarrhea among 39 Peace Corps volunteers during their first 5 weeks in Kenya. The volunteers took either doxycycline or placebo for 3 weeks and were observed for an additional 2 weeks. Nine of 21 taking placebo and 1 of 18 taking doxycycline had travelers' diarrhea during the treatment period ($p=0.012$). The protection seemed to persist for at least 1 week aft the drug was stopped. Enterotoxigenic *Escherichi coli* was the only pathogen isolated from the placebo group, but was not detected in persons takin doxycycline. None of these organisms were resist to doxycycline or tetracycline, whereas resistanc to tetracyclines and other antibiotics was common among the nonenterotoxigenic *E. coli*. It is concluded that doxycycline effectively prevented mos episodes of travelers' diarrhea.

6503 EFFECT OF A LACTOBACILLI PREPARATION O TRAVELER'S DIARRHEA: A RANDOMIZED, DOU BLIND CLINICAL TRIAL. (Eng.) de Dios Pozo-Olan J.; Warram, J. H., Jr.; Gomez, R. G.; Cavazos, M. G. (11602 Vantage Hill Rd., Reston, VA 22090). *Gastroenterology* 74(5, Part 1):829-830; 1978.

The effectiveness of prophylactic ingestion of a commercial preparation of lactobacilli (Lactinex for the prevention or modification of traveler's diarrhea was tested in a randomized double-blind clinical trial in 50 volunteer travelers to Mexi from the United States. Twenty-six subjects received the lactobacilli preparation, and 24 received placebo. The incidence of diarrhea and its duration during the 4 weeks of observation were similar for the two preparations: 35% for lactobacilli-treated subjects and 29% for placebo subjects. Typically, the diarrhea was mild, lasting 2 days. It is concluded that prophylactic ingestion of lactobacilli for 1 week

s not reduce the incidence or duration of
veler's diarrhea, either during the period of
estion or during the following 3 weeks.

4 FECAL STEROIDS IN DIARRHEA. II. TRAVELLERS' DIARRHEA. (Eng.) Huang, C. T. L.;
ll, J. N.; Merson, M.; Nichols, B. L. (Baylor
l. Medicine, Houston, TX 77030). *Am. J. Clin.*
r. 31(4):626-632; 1978.

investigate the hypothesis that fecal steroid
files may provide a means of biochemical differ-
iation among episodes of acute diarrhea caused
different etiological agents, fecal bile acid
neutral sterol patterns of five healthy adult
unteers from the United States who contracted
vellers' diarrhea (TD) in Mexico City in 1974
e studied by the collection and analysis of
al samples obtained during and either before
4 weeks after recovery. The only pathogen in
r of these patients was the heat-stable-only
erotoxin-producing strain of *Escherichia coli*.
ol culture for pathogens was negative in the
th subject. Bacterial 7α-dehydroxylation of
lic and chenodeoxycholic acids was not altered
diarrhea associated with toxigenic *E. coli*
t-stable, although total concentrations of bile
ds in the feces in mg/g of feces (wet weight)
e decreased during the diarrheal episode (1.3 ±
versus 3.3 ± 0.4 in controls, $p<0.02$). Con-
tent with findings on bile acids, no signifi-
t changes in the production of coprostanol from
lesterol were observed. Although total con-
trations of cholesterol metabolites, in mg/g of
es (wet weight), were reduced in diarrhea, the
ference was not significant statistically (2.2 ±
versus 5.4 ± 0.8 in controls, $p>0.05$). There
an apparent increase in bacterial alteration
fecal steroids in the subject who showed no
hogens in stool culture, despite a decrease in
al steroid concentrations of a magnitude similar
those observed in diarrhea associated with *E.*
i heat-stable. The production of coprostanol
correlated with 7α-dehydroxylation of cholic
d ($r=0.829$, $p<0.001$) and chenodeoxycholic acid
0.749, $p<0.001$). The results from this study
in striking contrast to the changes in gastro-
estinal steroid metabolism previously observed
acute shigellosis. In TD associated with ST-
coli, the ability of colonic flora to degrade
rols apparently remains intact, which may explain
lack of change in bacterial degradation of in-
tinal steroids observed in these patients.

5 VASOACTIVE INTESTINAL PEPTIDE AND THE WATERY DIARRHEA SYNDROME. (Eng.) Ebeid,
M.; Murray, P. D.; Fischer, J. E. (Massachusetts
eral Hosp., Boston, MA 02114). *Ann. Surg.* 187(4):
-416; 1978.

an effort to determine whether vasoactive
estinal peptide (VIP) is a mediator in the watery
rrhea syndrome, a sensitive and specific radio-
unoassay for the detection of VIP was used to
dy 180 healthy controls and various patients
h the watery diarrhea syndrome. Normal values for VIP were established as 42.8 ± 2.26 pg/ml in plasma (range 22-70 pg/ml). In 11 patients, the syndrome was associated with tumors, and plasma levels of VIP were elevated (210-2,100 pg/ml). VIP levels returned towards normal in five treated patients coincident with amelioration of symptoms. Normal values were obtained in patients with chronic pancreatitis, sprue, medullary carcinoma, Zollinger-Ellison Syndrome, and laxative abuse. In six other patients with an indistinguishable syndrome and no findings of tumor at laparotomy and autopsy, VIP levels were normal. The results suggest that VIP may be the causative agent in patients with the watery diarrhea syndrome and tumors, but that an indistinguishable syndrome exists for which VIP is not the cause.

6506 EOSINOPHILIC GASTROENTERITIS WITH OBSTRUCTION: IMMUNOLOGICAL STUDIES OF SEVEN PATIENTS. (Eng.) Caldwell, J. H.; Mekhjian, H. S.; Hurtubise, P. E.; Beman, F. M. (Ohio State Univ. Hosp., 410 W. 10th Ave., Columbus, OH 43210). *Gastroenterology* 74(5, Part 1):825-829; 1978.

Seven patients with eosinophilic gastroenteritis presenting with obstruction of the gastrointestinal tract were studied to characterize further this form of eosinophilic gastroenteritis. Five had required surgical treatment for relief of obstructive symptoms or because of diagnostic uncertainty. Immunological studies, including serum immunoglobulins, serum complement, lymphocyte quantitation, and lymphocyte response to nonspecific mitogens revealed no striking abnormalities. No patient was clinically allergic or food sensitive, and serum IgE was normal in all. A review of the literature since 1970 suggests that the obstructive form of eosinophilic gastroenteritis accounts for about half of the reported cases. Allergy, especially hypersensitivity to food, is not required for the diagnosis.

6507 GASTROINTESTINAL INVOLVEMENT IN NON HODGKIN'S LYMPHOMAS: 31 CASES. (Fre.) Najman, A.; Gorin, N. C.; Barranger, C.; Duhamel, G. (Hopital Saint-Antoine, 184, due du Fg Saint-Antoine, F 75571 Paris Cedex 12, France). *Nouv. Presse Med.* 6(38):3515-3519; 1977.

Gastrointestinal involvement was found in 31/200 patients with non-Hodgkin's lymphomas, and is a distinctive feature of this entity. Multiple lesions were present in 61% of the 31 patients; the gastroduodenal area was involved in 68%, the ileum in 45%, and the rectocolon in 61%. A diffuse histologic pattern was predominant (67%). Prolonged polychemotherapy is the treatment of choice, the specific agents depending upon clinical staging of the disease; in addition, radical surgery is indicated for patients in stages I_D or II_D. High energy irradiation (25 grays to the abdomen) may be associated with surgery and a short chemotherapeutic course for lymphosarcomas only. Among 24 patients with lymphosarcomas, the 24-month survival was 75%, and the median survival was 40 months. Of seven patients with reticulosarcomas, six died within 27 months. Relapses after treatment of primary gastrointestinal localization (8/12) always involved extradigestive tissues (lymph nodes, cavum, and bone).

6508 CALCIFIED PRIMARY TUMORS OF THE GASTROINTESTINAL TRACT. (Eng.) Ghahremani, G. G.; Meyers, M. A.; Port, R. B. (Evanston Hosp.-Northwestern Univ., 2650 Ridge Ave., Evanston, IL 60201). *Gastrointest. Radiol.* 2(4):331-339; 1978.

Experience with 23 primary calcified tumors of the gastrointestinal tract is presented; this information plus information from the literature were used to formulate guidelines for an accurate preoperative diagnosis of such tumors. Histopathologic diagnosis of the tumors was established by endoscopic biopsy, surgery, or autopsy. A retrocardiac mass containing amorphous calcifications was seen to be typical of leiomyoma of the esophagus. Calcific deposits similar to that in uterine fibroids may be the feature of gastric leiomyoma or intestinal leiomyosarcoma. Sand-like deposits within the wall of the stomach or colon were characteristic of a mucinous adenocarcinoma, while clusters of phleboliths in the gastrointestinal wall suggested a hemangioma, particularly if recurrent intestinal bleeding and cutaneous hemangiomas were associated. Sunburst type of calcification in the pancreas indicated a cystadenoma or cystadenocarcinoma of that organ, and aggregates of granular calcifications in the liver were diagnostic for metastatic adenocarcinoma of the colon, but were rarely seen in a primary liver malignancy.

6509 PREVALENCE OF ENDOCRINE ABNORMALITIES IN PATIENTS WITH THE ZOLLINGER-ELLISON SYNDROME AND IN THEIR FAMILIES. (Eng.) Lamers, C. B.; Stadil, F.; Van Tongeren, J. H. (St. Radboud Hosp., Nijmegen, Netherlands). *Am. J. Med.* 64(4):607-612; 1978.

To evaluate the frequency of associated and hereditary endocrinopathies in the Zollinger-Ellison syndrome, 10 patients with the syndrome and 109 family members over 15 yr of age were studied. In 7 of the 10 patients, coexisting endocrine disease was found. In six, the Zollinger-Ellison syndrome was probably a feature of multiple endocrine adenomatosis type 1, whereas Cushing's syndrome in the remaining patient may have been caused by the production of an ACTH-like substance by a mixed pancreatic tumor. All six patients with evidence of multiple endocrine adenomatosis type 1 had relatives with endocrinopathies. In the families of the four other patients with the Zollinger-Ellison syndrome, no endocrine abnormalities were found. During this study, 4 new cases of pituitary tumor, 17 of hyperparathyroidism, 7 of the Zollinger-Ellison syndrome, and 1 of insulinoma were detected. Although most of the disorders were asymptomatic, this clearly indicates that patients with the Zollinger-Ellison syndrome and their families should undergo detailed endocrine studies.

GENERAL

Parasitology

6548 HYDATID DISEASE OF THE LIVER. (Eng.) Barros, J. L. (Hosp. Provincial, Madrid, Spain). *Am. J. Surg.* 135(4):597-600; 1978.

Experience in the surgical management of hydatid disease of the liver in 212 patients over the past 18 yr is reviewed. There was associated pathologic disease of the biliary tract in 47 patients. The most common preoperative complication was rupture into the bile ducts (36 patients). Upper abdominal pain was the most common symptom, and a palpable mass or hepatomegaly was present in two-thirds of the patients. Liver scanning with radioactive isotopes was the most helpful routine diagnostic aid, the results being positive in 91% of the patients. The most common surgical treatment used (148 patients) consisted of removing the parasite (cystectomy) and treatment of the residual pericysti
cavity. Pericystectomy involved en block resect
of the intact cyst with the entire pericystic la
and was employed in 28 patients. Cholecystecto
was performed in 9 of the 47 patients with bili
tract disease, removal of common duct stones in
and evacuation of intraductal membranes in 4. I
ternal drainage into the gastrointestinal tract
performed in 14 patients with major bile fistul
to the pericystic cavity. Pericystojejunostomy
with a Roux-en-Y anastomosis of jejunum, was pe
formed in 11 patients, and pericystogastrostomy
carried out in 3. The results of therapy were

lent in 96% of patients with simple cysts. There
e eight deaths: four occurred in patients with
tured hepatopulmonary cysts, one was due to
phylactic shock after traumatic rupture of a
t, and two were due to terminal hepatic failure
rrhosis) and bleeding esophageal varices. One
raoperative death was ascribed to formalin tox-
ty. Postoperative infections occurred in 29
ients, and recurrent intra-abdominal disease was
ate complication that occurred in 18 patients.
servative excision of solitary or multiple cysts
recommended for most patients with hydatid liver
ease. It is important to establish whether hep-
c cysts communicate with the biliary tree, and
associated biliary disease should be taken
e of at the same time. In patients in whom the
t has penetrated the diaphragm and communicates
h the lung, treatment should be carried out in
stage whenever possible.

Regional Enteritis

6 PROGNOSIS IN CHILDREN WITH CROHN'S DIS-
EASE. (Eng.) Gryboski, J. D.; Spiro,
M. (Yale Univ. Sch. Medicine, 333 Cedar St.,
Haven, CT 06510). *Gastroenterology* 74(5, Part
807-817; 1978.

gain information on the prognosis of Crohn's
ease in children, the course of 86 children
h Crohn's disease was examined during a 10-yr
iod, between 1966 and 1976. Patients were
ssified according to the initial site of dis-
e. Ileocolitis was the most (52%) common and
itis the least (9%) common form of disease
h diffuse small bowel or ileal disease each
prising nearly 20% of the study group. These
ures show a reversal from those of a previous
ade, when 42% of the patients had only terminal
ileal disease and 17% had ileocolitis. Children with ileocolitis had the highest number of extracolonic manifestations and operations and required steroid therapy the longest. Those with only small bowel disease (with the exception of duodenal involvement) had fewer extraintestinal symptoms and operations and showed a consistently good response to medical treatment.

6557 THE VARIED MANIFESTATIONS OF CROHN'S DISEASE IN CHILDREN AND ADOLESCENTS. (Eng.) Dubois, R. S.; Rothschild, J.; Silverman, A.; Sabra, A. (Dept. Child Health, Univ. Sydney, Sydney, Australia). *Am. J. Gastroenterol.* 69(2):203-211; 1978.

Experience with 30 children less than 15 yr of age with histologically or radiologically proven Crohn's disease is reported. The mean age of onset was 9 yr and 5 months. Delay in diagnosis may stem from the varying modes of presentation. The mean delay in diagnosis was 2 yr. Chronic diarrhea and/or recurrent abdominal pain associated with extraintestinal manifestations, particularly abnormalities of growth and development, suggests the possibility of Crohn's disease in the pediatric age group. Involvement of the terminal ileum occurred in 29 of the 30 patients. In addition, colonic disease occurred in 13 and jejunal involvement in 1. Four patients presented with an acute onset of their disease; a favorable response to either medical or surgical therapy occurred in all four. Twenty-six patients had an insidious onset and tended to have a chronic course despite either medical and/or surgical therapy. Thirteen patients had an intestinal resection, with recurrence occurring in three from 1-4 yr postoperatively. To date there has been one death.

6558 A COMPARISON OF THE STRUCTURE AND FUNCTION OF THE TERMINAL ILEUM IN CROHN'S DISEASE USING RADIOLOGY, THE "DICOPAC" SCHILLING TEST AND [^{14}C]G.C.A. BREATH TEST.

(Eng.) Glover, S. C.; Mowat, N. A. G. (Dept. Medicine, Univ. Aberdeen, Aberdeen, Scotland). *Eur. J. Nucl. Med.* 3(2):121-124; 1978.

Terminal ileal function was measured by a glycholic acid (GCA) breath test and judged by radiological appearance, and the results were compared to determine whether the breath test might provide additional evidence of terminal ileal disease in patients with Crohn's disease. Twenty patients with biopsy-proven Crohn's disease were studied. Thirteen had radiological evidence of involvement of the terminal ileum. None had significant bacterial overgrowth of the small bowel contents, and none had had resection of the terminal ileum. In all patients, a ^{14}C-GCA breath test and a "Dicopac" Schilling test were performed to assess terminal ileal function (26 patients with functional diarrhea and 44 healthy subjects served as controls for the latter test). The data showed poor correlation between the radiological appearance of the terminal ileum and the results of the functional tests (6/10 patients with abnormal function tests also had abnormal radiological appearance; 7/10 patients with normal function tests had abnormal radiological appearance). There was also poor correlation between the results of the ^{14}C-GCA breath test and the "Dicopac" Schilling test (the tests agreed 11/20 times, of which 10 findings were normal). Without terminal ileal histology, any assessment of the extent of Crohn's disease of the terminal ileum and of its effect on terminal ileal function must include the ^{14}C-GCA breath test as well as radiology and the "Dicopac" Schilling test. The limitations of the ^{14}C-GCA breath test as a test of terminal ileal function in Crohn's disease are discussed.

6559 PLATELET KINETICS IN CROHN'S DISEASE.

(Eng.) Bremer, G.; Jacobi, E.; Miller, B.; Ehms, H.; Strohmeyer, G. (2. Medizinische Klinik u Polikinik der Universitat, Moorenstrasse 5, D-4000 Dusseldorf, W. Germany). *Klin. Wochenschr.* 56(7): 365-367; 1978.

To investigate the pathogenesis of thrombocytosis in Crohn's disease, 10 nontreated patients were examined and compared with 10 healthy controls using the ^{51}Cr-labeling technique. There was a si nificant elevation of platelet count in the patien compared with the controls (550,000 ± 150,000/µl versus 15,000-300,000/µl, $p<0.001$). The average platelet survival time was significantly shortened in the patients compared with the controls (6.9 days versus 9 days, $p<0.001$). Organ scanning for surface radioactivity revealed no differences between the two groups, indicating that neither stor ing nor sequestration occurred in any of the organ examined (heart, liver, spleen, and bone marrow); the recovery rate for injected ^{51}Cr activity was 55-60%. Platelet turnover was markedly accelerate in the patients (95,000/µl/day) compared with the controls (25,000/µl/day). Platelet function, meas ured as adhesiveness in the fiber test, was depressed in Crohn's disease compared with controls when the differences in platelet count between the two groups was considered. Platelet production is augmented in Crohn's disease and exceeds the reduced survival time. The increased thrombopoiesis may lead to the production of platelets with a physiological defect and so to increased periphera elimination. The elevated platelet production remains unexplained. It might be due to the possibl thrombopoietic action of certain humoral transmitt substances present only in Crohn's disease.

6560 COMPARISON OF THE RESULTS OF RESECTION, BYPASS, AND BYPASS WITH EXCLUSION FOR ILEOCECAL CROHN'S DISEASE.

(Eng.) Homan, W. P.; Dineen, P. (New York Hosp.-Cornell Medical Center New York, NY). *Ann. Surg.* 187(5):530-535; 1978.

The course of 161 patients with Crohn's disease s over a 43-yr period who underwent primary surgery for the disease is reviewed to determine the most liable treatment method. Resection was performed 115 patients, bypass with exclusion in 25, and si to-side ileotransverse colostomy in 21. Overall currence rates were 25% for resection, 63% for by with exclusion, and 75% for simple bypass. At 15 follow-up, recurrence rates were 65% for resectio 82% for bypass with exclusion, and 94% for simple pass. The superiority of resection over either b is significant ($p<0.005$ at 5 yr). Much of the di ference in final outcome was accounted for by ear recurrence or by persistent disease in the two bypass groups. This difference amounted to 21% for the bypass with exclusion and 45% for simple bypa as compared with 3% for patients who had resectio It is concluded that (1) resection can be perform with a morbidity and mortality equivalent to eith of the bypass procedures, (2) the recurrence rate following resection is significantly lower than b pass with exclusion or simple bypass and amounts about 4% per year, (3) continuing disease in the bypassed loop accounts for a high percentage of r

rations in the bypass groups, while appearance
new disease is the usual problem following re-
tion, and (4) resection is the surgical treatment
choice for ileocecal Crohn's disease.

51 ORAL 25-HYDROXYVITAMIN D$_3$ IN TREATMENT OF
OSTEOMALACIA ASSOCIATED WITH ILEAL RESEC-
ON AND CHOLESTYRAMINE THERAPY. (Eng.) Compston,
E.; Horton, L. W. L. (St. Thomas' Hosp., London
., England). *Gastroenterology* 74(5, Part 1):900-
; 1978.

ause the therapeutic applications of vitamin D
abolites and analogues have recently become of
siderable interest, the use of p.o. 25-hydroxy-
amin D$_3$ (25-OHD$_3$) in a woman with Crohn's dis-
e who developed severe histological osteomalacia
r after ileal resection and the start of choles-
amine therapy (4 g, 2x/day). Treatment with
OHD$_3$ (50 μg/day) produced marked biochemical,
iological, and histological improvement after
onths. It is suggested that cholestyramine, by
ucing vitamin D absorption, precipitated the
id development of osteomalacia in this patient.
s case report emphasizes the importance of rou-
e vitamin D supplementation in all patients on
g-term cholestyramine therapy, and indicates
t even in patients with small intestinal disease
resection, p.o. preparations of vitamin D or its
abolites and analogues may be effective.

52 ANKYLOSING SPONDYLITIS AND INFLAMMATORY
BOWEL DISEASE. I. PREVALENCE OF INFLAM-
ORY BOWEL DISEASE IN PATIENTS SUFFERING FROM
YLOSING SPONDYLITIS. (Eng.) Meuwissen, S. G.
Dekker-Saeys, B.; Agenant, D.; Tytgat, G. N. J.
ept. Medicine, Univ. Amsterdam, Amsterdam, Nether-
ds). *Ann. Rheum. Dis.* 37(1):30-32; 1978.

establish the prevalence of inflammatory bowel
ease in ankylosing spondylitis (AS), 79 AS pa-
nts underwent detailed medical screening, in-
uding sigmoidoscopy and roentgenology. Forty-
ght patients had gastrointestinal symptoms,
the others did not. In three patients, a
agnosis of Crohn's disease was made, which
been previously established. In all other
ients inflammatory bowel disease was excluded.
prevalence of inflammatory bowel disease in
s series of patients with AS therefore was 3.8%.
ere were two patients without Crohn's disease in
m distal rectal pathology was attributed to
al anti-inflammatory treatment. It appears that
ominal symptoms in most of the patients with AS
e not related to inflammatory bowel disease, but
bably to an irritable bowel syndrome.

53 ZINC DEFICIENCY IN CROHN'S DISEASE. (Eng.)
Solomons, N. W.; Rosenberg, I. H.; Sand-
ead, H. H.; Vo-Khactu, K. P. (Inst. Nutrition
tral America and Panama, Carretera Roosevelt,
Zona 11, Apartado 11-88, Guatemala City, Guatemala). *Digestion* 16(1/2):87-95; 1977.

Zinc nutrition was studied using plasma zinc, hair zinc, and taste acuity as indices in 20 adult patients (20-62 yr old) and in 10 adolescent patients (10- to 19-yr old), all of whom were classified as having Crohn's disease (either regional enteritis, ileocolitis, or granulomatous colitis), and the results were compared with those in 20 control adults and 39 control adolescents. The adult patients had a mean plasma zinc concentration of 62.3 ± 9.3 μg% compared with 74.3 ± 9.7 μg% in the controls. Adolescent controls had a mean plasma zinc concentration of 78.6 ± 17.6 μg% compared with 46.2 ± 12.6 μg% ($p<0.001$) in the five adolescent patients with growth retardation or delayed sexual maturation and 75.2 ± 27.7 μg% in the five adolescent patients who maintained normal growth patterns. There was no significant difference between the plasma zinc levels of the 13 adult patients who were taking steroids and the 7 who were not. There was a strong correlation between plasma zinc concentrations and plasma albumin levels for the 20 adult controls, the 20 adult Crohn's patients, and the 5 growth-retarded adolescents ($p<0.001$). Hair zinc content in Crohn's disease tended to be low, but was without the statistical significance observed for plasma zinc. The mean score in the taste detection test of -6.6 ± 4.8 for the 20 adult Crohn's patients was significantly lower ($p<0.001$) than the adult control mean of -2.0 ± 1.5. The mean taste detection score for the five growth-retarded adolescents was -5.2 ± 4.8 compared with -0.8 ± 1.0 for the control adolescents ($p<0.001$). It is concluded that zinc deficiency commonly exists in patients with Crohn's disease and that the low plasma zinc concentrations may reflect a reduction of plasma zinc-binding protein (albumin) due to gastrointestinal loss and/or impaired synthesis.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

Scientific Communications Officer
Gastroenterology Abstracts and Citations
National Institute of Arthritis, Metabolism and Digestive Diseases
National Institutes of Health
Building 31, Room 9A-21
Bethesda, Maryland 20014

Other individuals and libraries may receive this publication by subscribing *directly* to the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

AUTHOR INDEX

SUBJECT INDEX

The Secretary of the Department of Health, Education, and Welfare has determined that the publication of this periodical is necessary in the transaction of the public business required by law of this Department. Use of funds for printing this periodical has been approved by the Director of the Office of Management and Budget through April 30, 1981.

For sale by the Superintendent of Documents, U.S. Government Printing Office, Washington, D.C. 20402. Subscription price per year in the United States and its possessions: $27.00 (this includes index issue); foreign, $6.75 additional. Single copy price is $1.90 domestic and $2.40 foreign. The index issue is $3.45 domestic and $4.35 foreign. Payment is required in advance, and check or money order should be made payable to the Superintendent of Documents.

NOTE

Journal names are abbreviated according to the list of abbreviations used by *Index Medicus*. For journals not covered by *Index Medicus*, the abbreviations (with some modifications) found in *International Standard ISO833, 1974*, are used. The two-letter state abbreviations are based on the United States Postal Service Code.

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

6568 IMMUNOHISTOCHEMICAL IDENTIFICATION OF GASTROINTESTINAL NEUROTENSIN CELLS IN HUMAN EMBRYOS. (Eng.) Helmstaedter, V.; Muhlmann, B.; Feurle, G. E.; Forssmann, W. G. (Anatomisches Institut der Universitat, Im Neuenheimer Feld 307, D-6900 Heidelberg, W. Germany). *Cell Tissue Res.* 184(3):315-320; 1977.

The development of the endocrine gastroenteropancreatic (GEP) system was studied in 10 human embryos (4-21 weeks), with special reference to neurotensin-immunoreactive cells. These cells were first present in the ileal and jejunal mucosa of 12- to 13-week-old embryos. Thereafter, the neurotensin-immunoreactive cells were found regularly in these segments of the gut with an increasing number of them towards the terminal ileum. At about the 20th week of gestation, the neurotensin cells were detected also in the lower duodenum, i.e., the distribution pattern was more extensive at this age than in younger embryos or adults. The cells were of triangular or elongated shape and their apical pole reached the gut lumen, and they thus looked like other types of small intestinal endocrine cells.

6569 ULTRASTRUCTURE OF THE HUMAN ANTRAL G CELLS DURING FASTING. (Eng.) Zaviacic, M.; Brozman, M.; Jakubovsky, J.; Duris, I. (Inst. Pathology, Komensky Univ., Sasinkova 4, 80100 Bratislava, Czechoslovakia). *Exp. Pathol. (Jena)* 14(3/4):131-135; 1977.

To study the influence of fasting on the ultrastructure of the human antral G cells, six healthy men who were fasted for 24 hr, a seventh (heavier than average weight) who was fasted for 240 hr, and two controls were examined by gastrobiopsy carried out without morphine or atropine. The biopsy material was prepared immediately for electron microscopy. In the controls and in the subjects fasted for 24 hr (3 had water and 3 did not), G cells with granules of different densities and with emptied granules were found; the numerical ratio of the dense and emptied granules was variable. Dense lysosomes were rarely seen in these cells. The subject who was fasted for 240 hr was examined at both 72 and 240 hr. At both times, the G cells had mostly emptied granules. In some of the granules, small residues of contents were observed. The membrane of the granules was preserved. Emiocytosis did not occur. At 240 hr, dense lysosomes with engulfed granules were seen. The authors believe that the dissolution of the granules in the G cells was due to the long fasting and not to the mechanical irritation of the gastrobiopsy technique. The role of psychic stress during fasting cannot be estimated in this experiment.

6570 CULTURE OF ISOLATED SMOOTH MUSCLE CELLS OF RAT DUODENUM. (Fre.) Miachon, S.; Biol, M. C.; Cier, J. F.; Chardonnet, Y. (UER Medicale Grange Blanche, 8 avenue Rockefeller, 69373 Lyon Cedex 2, France). *C.R. Soc. Biol. (Paris)* 171(4):804-808; 1977.

Smooth muscle cells were isolated from Sprague-Dawley rat duodena by either trypsinization (0.2%) or collagenation (0.05%) and cultured to study their catecholamine receptors. The cells were cultured in either Eagles' minimum essential medium (MEM) with glutamine and nonessential amino acids or medium RPMI 1640 (from Gibco), both with 10% fetal calf serum. Transfers were attempted on the 15th day (the cells were confluent) by mechanical means and/or trypsinization. The best results were achieved when trypsinization was used to isolate the cells; there was no difference in results between the two culture media. At the beginning, the cultures consisted mainly of smooth muscle cells and a few fibroblasts; on day 5, myofibrils were identifiable in 20% of the cells, and on day 12, in 2%. Two transfers were performed over a period of 50 days, although very few cells could be induced to grow again. Trypsinization only was the least damaging method of cell transfer. Myofibrils were not demonstrable in any of the transferred cells. In view of the rapid dedifferentiation and low yield of cells, this method is, at present, rather unsuitable for the study of receptor sites.

ABSORPTION - EXCRETION - TRANSPORT

6580 FAILURE OF GLUCAGON TO INFLUENCE ION TRANSPORT ACROSS HUMAN JEJUNAL AND ILEAL MUCOSA IN VITRO. (Eng.) Isaacs, P. E. T.; Turnberg, L. A. (Hope Hosp., Eccles Old Rd., Salford, M6 8HD, England). *Gut* 18(12):1059-1061; 1977.

To assess whether glucagon-stimulated intestinal secretion is due to a direct effect on mucosal ion transport or is secondary to motility and blood flow changes, the influence of glucagon on human intestinal mucosa was studied *in vitro* where these complicating factors are eliminated. Stripped human intestinal mucosa from surgical specimens was used. The mucosal potential difference (PD), short-circuit current (SCC), and resistance (R) tended to fall in all tissues tested, and there was no difference between controls and glucagon-treated (0.2, 0.5, 1.0, or 2.0 ng/ml) tissues. Measurement of ion fluxes in jejunal and ileal mucosa revealed that glucagon (0.2-2.0 ng/ml) did not influence ion transport in either tissue. Net sodium absorption in the presence of glucose was greater in ileal than in jejunal tissues. Net chloride transport was not significantly different from zero in jejunal tissues, but there was a marked absorption of chloride in most ileal tissues. These results confirm previous reports of differences between the *in vitro* behavior of jejunal and ileal mucosa and suggest that the intestinal secretion and diarrhea produced *in vivo* in man during i.v. infusion of glucagon may be produced by changes in motility and blood flow.

6581 MECHANISMS OF TRANSPORT OF Na, Cl, AND K IN THE HUMAN COLON. (Eng.) Hawker, P. C.; Mashiter, K. E.; Turnberg, L. A. (Hope Hosp., Eccles Old Rd., Salford M6 8HD, Lancashire, England) *Gastroenterology* 74(6):1241-1247; 1978.

In view of the apparent discrepancies between species in colonic transport, ionic transport across isolated, stripped, human colonic mucosa was studied *in vitro* using a modified short circuit current technique. Electrical potential difference and short circuit current were dependent on the presence of sodium ions in the mucosal bathing solution and were unaffected by addition of 10 mM glucose to the solution. Ouabain (10^{-3} M) added to the serosal reservoir abolished both potential difference and short circuit current. Isotopic flux measurements across short-circuited colonic mucosa showed a net active sodium absorption that accounted for the observed short circuit current and was unaffected by 10 mM glucose. Chloride was also actively absorbed and this was unaffected by removal of sodium from the bathing solutions. Ouabain abolished net sodium absorption but had no effect on chloride absorption. There was a net active secretion of potassium that was abolished in sodium-free buffer. It is concluded that sodium is actively absorbed via a rheogenic process that is not stimulated by glucose; chloride is actively absorbed via a nonelectrogenic process, not linked to sodium transport, and probably involving a $Cl^-HCO_3^-$ exchange; and potassium is actively secreted possibly via a Na^+K^+ exchange.

6582 EFFECTS OF DIETARY PROTEIN ON BODY WEIGHT MUCOSAL GROWTH, AND CALCIUM ABSORPTION

IN THE RAT. (Eng.) Moyer, G. L.; Wilson, H. D.; Schedl, H. P. (Univ. Iowa Coll. Medicine, Iowa City, IA 52242). *Am. J. Dig. Dis.* 23(6):545-549; 1978.

To determine whether a duodenal or ileal calcium transport response could account for decreased fecal calcium excretion reported in rats fed high-protein diets, calcium transport by these two segments was examined directly by *in situ* perfusion. Weight-matched growing rats were pair-fed isocaloric diets for 6-8 days containing 89% protein (casein), 39% protein, or 0% protein. Sucrose was substituted for the decreased casein in the 39% and 0% protein diets. Each diet also contained 5% fat, a mineral mix, and vitamins. Calcium content of all diets was 0.5%. Body weight was maintained by the 39% protein group; weight loss was 5% for the 89% protein group and 18% for the 0% protein group. Small intestinal weight as a percentage of body weight was the same for the three groups. For both the duodenum and the ileum, mucosal dry weight was greater in the 39% protein group (11.0 ± 0.3 and 7.6 ± 0.2 mg/cm, resp.) than either the 89% protein (9.6 ± 0.4 and 6.4 ± 0.3 mg/cm, resp.) or 0% protein group (9.2 ± 0.3 and 5.9 ± 0.3 mg/cm, resp). Calcium absorption per gram dry weight of mucosa (absorptive specific activity) was the same for all diet groups, but because of the greater mucosal weight per unit length in the 39% protein group, absorption per centimeter was increased in this group. Although no direct relation between dietary protein and mucosal absorptive specific activity for calcium was found, calcium absorption was determined by the amount of mucosa that was dependent on protein intake and reflected the nutritional status of the body.

6583 THE EFFECT ON INTESTINAL CALCIUM ABSORPTION OF SOMATOSTATIN IN MAN. (Eng.)

Evensen, D.; Hanssen, K. F.; Berstad, A. (Aker Hosp., Oslo 5, Norway). *Scand. J. Gastroenterol.* 13(4):449-451; 1978.

The effect of somatostatin on intestinal calcium absorption was investigated in nine healthy subjects to determine whether the action of the hormone is related to its ability to interfere with calcium transport mechanisms. Using an isotope method with ^{51}Cr as a stool marker, the absorption of ^{47}Ca was measured with and without an i.v. infusion of cyclic somatostatin (250 μg/hr, 2 hr). Net absorption fell from 53.0 ± 14% without the infusion to 40.4 ± 13% with somatostatin ($p<0.05$). The results suggest that the actions of somatostatin may be mediated via an inhibition of active calcium transport.

6584 GLUCOSE TRANSPORT BY RAT SMALL INTESTINE AFTER EXTENSIVE SMALL-BOWEL RESECTION.

(Eng.) Urban, E.; Haley, D. P. (Audie L. Murphy Memorial Veterans Hosp., 7400 Merton Minter Blvd., San Antonio, TX 78284). *Am. J. Dig. Dis.* 23(6): 531-540; 1978.

Glucose transport by the rat small intestine was studied after extensive bowel resection. Fifty centimeters of proximal or distal small intestine were resected, preserving duodenum and terminal ileum. Glucose transport was studied 5-6 weeks later, using everted gut sacs from duodenum, ileum, and also from a midgut segment consisting of intestine located preresection at mid-small intestine. Sham-operated animals served as controls. In controls, the inner (serosal) fluid medium in sacs from duodenum and midgut gained glucose; ileal sac serosal medium lost glucose. Proximal resection resulted in significant growth of duodenal and midgut mucosa ($p<0.05$). Duodenal transport specific activity decreased from control values (from 77.5 ± 9.8 to 36.2 ± 4.7 μmol/g dry mucosa in 1 hr), but mucosal growth compensated so sac transport capacity (transport/cm sac length) remained unchanged. Midgut transport specific activity remained unchanged; thus sac transport capacity directly mirrored increased mucosal mass. Ileal sac serosal medium now accumulated glucose; there was no mucosal growth. Transport specific activity and sac transport capacity of ileum increased in parallel. After distal resection, there was no alteration of either duodenal and midgut mucosal masses or transport specific activities; hence sac transport capacities remained unchanged. Ileal sac serosal medium also accumulated glucose, but now both transport specific activity and mucosal mass increased. The resultant increased sac transport capacity was identical to that of ileum after proximal resection. In all sacs from control and resected animals, uphill ^{14}C-glucose concentration differences developed between medium and mucosa. Activity of the mucosal uptake process, assessed in terms of a ratio of mucosal intracellular fluid radioactivity to mucosal medium radioactivity, usually mirrored altered transport specific activity. This indicates that the increased undercoats tissue mass that accompanied increased mucosal mass did not critically affect transport. The most striking findings were: (1) decreased duodenal transport specific activity after proximal resection with mucosal growth compensating and (2) identical adaptations of ileal segment transport capacities after either proximal or distal small bowel resections, although mechanisms differed. The present study provides a base for further examinations of carrier-mediated nexose transport after extensive loss of small intestine.

6585 ASCORBATE STIMULATION OF SALICYLATE ABSORPTION IN ISOLATED RAT INTESTINE.

(Eng.) Barnett, G.; Lockwood, T.; Arancibia, A.; Benet, L. Z. (Natl. Inst. on Drug Abuse, Rockville, MD 20857). *J. Pharm. Sci.* 67(2):224-226; 1978.

The interaction of ascorbate with salicylate transport across the isolated rat intestine was studied *in vivo* and *in vitro*. *In vitro,* the flux of labeled salicylate from the mucosal to the serosal side of the tissue was measured before and after ascorbate was added to the serosal solution. Salicylate reached a new steady-state flux after ascorbate addition over a concentration range of 1-57 mM. The tissue permeability had a saturable dependence on ascorbate concentration. Ascorbate (6 mM) also increased the short-circuit current by 13%, with onset immediately after ascorbate addition to the medium and with leveling to a constant value at 70 min. This stimulatory effect was essentially due to a decrease in tissue resistance, suggesting that the effect of ascorbate treatment on electrical properties is different from those of theophylline or ouabain. Similar results were obtained *in vivo*.

6586 INTESTINAL THIAMIN [sic] TRANSPORT: EFFECT OF CHRONIC ETHANOL ADMINISTRATION IN RATS. (Eng.) Hoyumpa, A. M., Jr.; Nichols, S.; Henderson, G. I.; Schenker, S. (Veterans Admin. Hosp., Nashville, TN 37203). *Am. J. Clin. Nutr.* 31(6):938-945; 1978.

The effect of chronic ethanol treatment on intestinal thiamine transport was studied in female Sprague-Dawley rats. The rats were fed the DeCarli-Lieber ethanol diet for 6 to 8 weeks, and ^{14}C-thiamine uptake and exit from enterocytes were measured in inverted gut sacs and correlated with basolateral membrane Na-K ATPase activity. The thiamine transport rate and Na-K ATPase activity were not affected in chronic ethanol-treated rats compared to pair-fed controls. Ethanol concentrations in gut lumen and plasma at the time of the study were 39.3 ± 15.3 and 40.2 ± 19.4 mg/100 ml, resp., although higher levels were noted at other times. Tissue thiamine pyrophosphate remained normal. In contrast, ethanol-treated rats given an extra dose of ethanol intragastrically (250 mg/100 g body weight) 1 hr before study showed a decrease in cellular exit of 0.2 and 0.5 μM thiamine to 44% and 56% of control, resp., ($p<0.025$) and of Na-K ATPase to 32% of control ($p<0.001$) when gut and plasma ethanol levels were 318.3 ± 38.7 and 185.0 ± 8.7 mg/100 ml, resp. These studies (a) confirm the inhibitory effect of ethanol on thiamine transport, (b) show that inhibition is dependent more on the ethanol concentration than on the duration of exposure to ethanol, and (c) suggest that thiamine malabsorption in this animal model may be intermittent. These findings may be relevant to the development of thiamine deficiency in alcoholics with periodic binge drinking.

MOTILITY

6599 RELATION BETWEEN VOLUME SWALLOWED AND VELOCITY OF THE BOLUS EJECTED FROM THE PHARYNX INTO THE ESOPHAGUS. (Eng.) Fisher, M. A.; Hendrix, T. R.; Hunt, J. N.; Murrills, A. J. (Guy's Hosp. Medical Sch., London, England). *Gastroenterology* 74(6):1238-1240; 1978.

The velocity of the front face of a liquid saline bolus ejected from the pharynx into the esophagus was measured by recording changes of luminal electrical impedance with three sets of electrodes in nine healthy subjects. At a site 26 cm from the incisors, the mean velocity of the front face of the bolus increased from 10 to 70 cm/sec as the volume swallowed was raised from 5 to 30 ml. The velocity of the front face of the bolus was greater 26 cm from the incisors than it was 32 cm from the incisors. These findings demonstrate that the greater the volume of the bolus, the greater the velocity of ejection.

6600 ALTERED LOWER ESOPHAGEAL SPHINCTER FUNCTION DURING EARLY PREGNANCY. (Eng.) Fisher, R. S.; Roberts, G. S.; Grabowski, C. J.; Cohen, S. (Temple Univ. Hosp., 3400 N. Broad St., Philadelphia, PA 19140). *Gastroenterology* 74(6): 1233-1237; 1978.

To determine whether lower esophageal sphincter (LES) function is normal during early pregnancy, studies were performed in eight pregnant women before and after abortion. Resting LES pressures were 22.1 ± 2.4 and 22.6 ± 2.3 mm Hg before and after abortion, resp. During early pregnancy, the LES pressure responses to pentagastrin (1.0 μg/kg) were inhibited significantly ($p<0.001$), compared with that 6 weeks after abortion. The LES responses to edrophonium and methacholine were decreased also ($p<0.02$ in both cases). LES pressure responses to a protein meal were diminished in an additional five pregnant women. Serum concentrations of estrogen and progesterone were elevated during pregnancy, but the serum concentration of gastrin was unchanged. It is concluded that, in early pregnancy, the basal LES pressure was within normal limits, but the LES pressure responses to hormonal, pharmacological, and physiological stimulation were reduced (during demonstrated elevations of serum concentrations of estrogen and progesterone). These studies suggest that during early pregnancy, when no clinical symptoms of reflux are present, altered LES function may be demonstrated.

6601 EFFECT OF INTRAGASTRIC BILE ON CANINE LOWER OESOPHAGEAL SPHINCTER PRESSURE. (Eng.) Laitinen, S.; Mokka, R. E. M.; Larmi, T. K. I. (Univ. Central Hosp., SF-90220, Oulu 22, Finland). *Scand. J. Gastroenterol.* 13(3):369-372; 1978.

A study was carried out to elucidate the immediate effect of intragastrically instilled bile on lower esophageal sphincter pressure (LESP) in the dog. Seven mongrel dogs were studied manometrically under thiopentone anesthesia. Resting LESP and intragastric pH were determined, after which 5 ml of fresh canine bile or of physiological saline (control) were instilled into the stomach and changes in LESP and intragastric pH were recorded for 1 hr. After bile instillation, LESP increased from 17.6 ± 2.3 to 26.4 ± 3.6 mm Hg ($p<0.01$) in 20 min and then gradually returned to the initial level by 60 min. The pH of the bile and saline were 7.7 ± 0.2 and 7.0 ± 0.1, resp. After bile instillation, intragastric pH rose from 2.7 ± 0.3 to 3.0 ± 0.4 and after saline instillation from 2.7 ± 0.3 to 3.0 ± 0.3. The results suggest that intragastric bile contamination, at least one of short duration, does not have any harmful effect on LESP competence and does not seem to predispose to gastroesophageal reflux in dogs.

6602 INDUCTION OF GASTRO-OESOPHAGEAL REFLUX BY ALCOHOL. (Eng.) Kaufman, S. E.; Kaye, M. D. (Univ. Vermont Coll. Medicine, Burlington, VT 05401). *Gut* 19(4):336-338; 1978.

To establish whether alcohol in amounts customarily imbibed during social drinking causes gastroesophageal reflux, 12 healthy young individuals, without symptoms of reflux, were studied twice. Each time, distal esophageal pH was monitored continuously for 3 hr after a standard meal that included either 180 ml of 100 proof vodka or 180 ml water. The order of studies with and without alcohol was random. Peak blood alcohol concentrations ranged between 0.63 and 1.29 g/l. Eleven of the 12 subjects refluxed more after alcohol ($p<0.0034$), and the difference in mean reflux scores for studies with and without alcohol was highly significant ($p<0.0005$). It is concluded that relatively modest quantities of alcohol induce gastroesophageal reflux in healthy people.

6603 GASTRIC EMPTYING RATES OF SOLID FOOD IN RELATION TO BODY SIZE. (Eng.) Lavigne, M. E.; Wiley, Z. D.; Meyer, J. H.; Martin, P.; MacGregor, I. L. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 74(6):1258-1260; 1978.

The relationship of body size to rates of gastric emptying of solid food was investigated in nine healthy men to obtain data that may allow this variable to be considered when populations of varying size are studied. Rates of gastric emptying were measured using a beef stew meal to which were added pieces of chicken liver tagged with ^{99m}Tc-sulfur colloid and by following the passage of the isotope through the gastrointestinal tract with intermittent γ-imaging. There was an inverse linear relationship between gastric emptying rates and body surface area, and between gastric emptying rates and body weight. The variable of body size must be taken into account when measurements of gastric emptying of solid food are measured.

6604 A UNIQUE DISTRIBUTION OF LAXATIVE-INDUCED SPIKE POTENTIALS FROM THE SMALL INTESTINE OF THE DOG. (Eng.) Atchison, W. D.; Stewart, J. J.; Bass, P. (Sch. Pharmacy, Center for Health Sciences, 425 North Charter St., Madison, WI 53706). *Am. J. Dig. Dis.* 23(6):513-520; 1978.

The effects of castor oil and ricinoleic acid on small bowel electrical activity were studied in fasted conscious dogs and were compared to the effects elicited by two nonlaxative oils (triolein and oleic acid) to determine the mechanism of castor oil and ricinoleic acid laxation. Spike potential activity was monitored at two jejunal sites using unipolar recording electrodes. Castor oil, ricinoleic acid, and triolein (all 40 ml) produced an increased incidence of basic electrical rhythm (BER, $p<0.05$) with associated spike potentials when compared to a fasted control; however, the total electrical spiking activity produced by these oils was not statistically different from that induced by feeding. No treatment altered any of the characteristics of BER. A novel pattern of electrical spiking activity was observed in response to the laxatives. This pattern consisted of short repetitive bursts of spike potentials that migrated the length of the recording site. The laxative-induced electrical pattern persisted for several days after treatment with ricinoleic acid or castor oil, and interdigestive patterns were occasionally interrupted for as long as 72 hr. Electrical activity following feeding or the nonlaxative oils consisted of random spike potentials, and normal interdigestive electrical activity resumed within 24 hr. The laxative-induced electrical pattern was quantitatively distinct from those produced by feeding, fasting, or nonlaxative oils. This pattern may reflect an action of these laxatives on intestinal motility during a diarrheal state.

6605 PHARMACOLOGIC ANALYSIS OF PENDULUM TYPE MOVEMENTS APPEARING DURING THE CALCIUM INDUCED BLOCKADE OF PERISTALSIS IN ISOLATED GUINEA PIG ILEUM. (Fre.) Beleslin, D. (Faculty Medicine, 11000 Beograd, C.P. 662, Yugoslavia). *C.R. Soc. Biol. (Paris)* 171(4):746-750; 1977.

Isolated guinea pig ileum preparations subjected to constant intraluminal pressure to induce peristalsis were then exposed to an excess of $CaCl_2$ on the serosal side to study the induced pendular movements. The Ca^{++} ions (9.1-36.0 mM) blocked the peristalsis, but after 30 min provoked pendulum-like movements (1-7/min) of the longitudinal muscle layer that lasted several hours. The addition of hexamethonium (>100 µg/ml), tetraethylammonium (>100 µg/ml), morphine (1-2 µg/ml), methadone (2-20 µg/ml), and atropine (1-10 ng/ml) to the serosal side blocked the movements, while neostigmine (0.025 µg/ml) potentiated them. From the action of these drugs, it can be concluded that the excess Ca^{++} ions induced the pendular movements by stimulating the postganglionic nerve endings in the longitudinal smooth muscle layer of isolated guinea pig ileum.

6606 PHARMACOLOGIC ANALYSIS OF PERISTALTIC BLOCKADE INDUCED BY THE ADDITION OF MAGNESIUM TO THE SEROSAL OR MUCOSAL SIDES OF ISOLATED GUINEA PIG ILEUM. (Fre.) Beleslin, D.; Samardzic, R. (Faculty Medicine, 11000 Beograd, C. P. 662, Yugoslavia). *C. R. Soc. Biol. (Paris)* 171(4):750-754; 1977.

The effect of various cholinergic drugs on isolated guinea pig ileum was studied after peristalsis had been blocked by magnesium to determine whether their effect is observed when they are applied to either the serosal or the mucosal side. The addition of acetylcholine (100-10,000 µg), metacholine (10-100 µg), eserine (2-20 µg), and neostigmine (5-25 µg) to the serosal side of the ileum antagonized the blocking effect of Mg^{++} ions (2.7-10.8 mM) previously applied to the mucosa. The same effect occurred when choline esters and anticholinesterases were injected intraluminally after the Mg^{++} ions were applied to the serosal side. Histamine (20-100 µg) and 5-hydroxytryptamine (2-200 µg) were not capable of removing the Mg^{++} ion block. These results indicate that cholinoceptive sites within the myenteric plexus, which initiate peristalsis when stimulated with cholinergics, are accessible from either side of the isolated ileum.

6607 STRICTLY ADDITIVE ANTISPASMODIC EFFECTS OF PAPAVERINE AND TIEMONIUM: AN EXAMPLE OF SEQUENTIAL BLOCKADE. (Fre.) Labrid, C.; Dureng, G.; Bert, H. (Laboratoire de Pharmacodynamie, C.E.R.M., 63203 Riom Cedex, France). *C.R. Soc. Biol. (Paris)* 171(4):764-770; 1977.

The effects of the antispasmodics tiemonium and/or papaverine were studied in isolated guinea pig ileum stimulated with $BaCl_2$ or histamine and in isolated rat jejunum stimulated with acetylcholine. When tiemonium was added to the preparations in various concentrations, its competitive antagonism was clearly demonstrated by the parallel shift to the right of the dose response curves compared to controls where only $BaCl_2$, histamine, or acetylcholine was used. The noncompetitive antagonism of papaverine was shown by a decrease in the maximal amplitude of the dose-response curves compared to controls. When both papaverine and tiemonium were used to inhibit the contracting agents, their effect was strictly additive, causing both a shift to the right and a decrease in amplitude. These results indicate a sequential blockade by papaverine and tiemonium on the cholinergic, histaminergic, and Ba^{++} ion receptors of smooth muscle tissue.

6608 ENHANCEMENT OF ELECTRICALLY STIMULATED GUINEA-PIG GALLBLADDER CONTRACTION BY SUBTHRESHOLD CONCENTRATIONS OF GASTROINTESTINAL HORMONES IN VITRO. (Eng.) Foesel, S.; Sewing, K. F. (Dept. Pharmacology, Univ. Tubingen, Wilhelmstrasse 56, D-7400 Tubingen, W. Germany). *Experientia* 34(2):5-6; 1978.

Experiments were carried out to investigate how subthreshold concentrations of cholecystokinin-octapeptide (CCK-OP), pentagastrin (PG), or secretin (S) influence the effects of transmural electrical stimulation (to mimic vagal excitation) on the isolated guinea pig gallbladder. A significant increase in gallbladder contraction in response to electrical stimulation was found after subthreshold concentrations of PG ($13\text{-}73 \times 10^{-9}$ M, $p<0.05$) and CCK-OP ($2\text{-}4 \times 10^{-11}$ M, $p<0.01$). The slight increase after secretin was not statistically significant. Since contractions of the gallbladder in response to both electrical stimulation and acetylcholine were blocked by atropine almost to the same extent, electrical stimulation could be regarded as an equivalent to vagal stimulation *in vivo*. Concentrations of PG and CCK-OP that alone do not contract the isolated guinea pig gallbladder after exposure of the organ to subthreshold concentrations of the hormones do enhance contraction in response to electrical stimulation. Thus, even on a subthreshold level, a synergistic action of hormonal stimulation with neural stimulation is possible. Circulating concentrations of CCK, which alone are inactive, may facilitate gallbladder contraction elicited by nervous excitation. This cooperative action could allow the neuroendocrine system to operate on a more economic level.

6617 REGIONAL DISTRIBUTION OF PROSTAGLANDIN-METABOLIZING ENZYMES IN THE MUCOSA OF THE HUMAN UPPER GASTROINTESTINAL TRACT. (Eng.) Peskar, B. M. (Medizinische Klinik, Univ. Freiburg, 7800 Freiburg i. Br., W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 25(1):49-51; 1978.

To compare the specific activities of the prostaglandin (PG)-metabolizing enzymes 15-hydroxy-PG-dehydrogenase (15-HPGDH), $^{13}\Delta$-reductase (DR), and PG E-9-keto-reductase (PGEKR) in various regions of the human upper gastrointestinal tract, four to six mucosal biopsy specimens were obtained from each of 34 patients undergoing diagnostic endoscopy. Only macroscopically normal tissue was used, and the absence of pathological changes was confirmed histologically. Specimens from the esophagus, gastric fundus, gastric corpus, gastric antrum, and duodenum were analyzed. All three enzymes were found in all regions of the gastrointestinal tract examined, the 15-HPGDH specific activity being highest in every region and the PGEKR specific activity being the lowest. Variations from region to region in the activity of any enzyme were quite small. However, 15-HPGDH activity was significantly lower ($p<0.05$) in the esophagus than in the duodenum; the activity of PGEKR was significantly higher in the duodenum than in the gastric corpus ($p<0.01$), the gastric fundus ($p<0.001$), or the esophagus ($p<0.005$) and significantly lower ($p<0.005$) in the gastric fundus than in the esophagus. The results indicate that control of the biological activity of PGs in the human gastrointestinal tract by enzymatic inactivation is not restricted to only some regions, which suggests a fundamental function of endogenous PGs in the gastrointestinal tract.

6623 GASTRIN IN THE HUMAN FETUS: DISTRIBUTION AND MOLECULAR FORMS OF GASTRIN IN THE ANTRO-PYLORIC GLAND AREA, DUODENUM AND PANCREAS. (Eng.) Larsson, L. I.; Rehfeld, J. F.; Goltermann, N. (Inst. Medical Biochemistry, Univ. Aarhus, DK-8000 Aarhus C, Denmark). *Scand. J. Gastroenterol.* 12(7):869-872; 1977.

Evidence that neonatal and fetal gastrin is secreted into the blood stream prompted an immunocytochemical and radioimmunochemical evaluation of the development of gastrin in the antrum, duodenum, and pancreas in 11- to 12-week-old fetuses. Pancreatic gastrin was not detected at any of the ages studied. Antral gastrin cells were numerous only in fetuses older than 19 weeks, whereas many strongly immunoreactive gastrin cells were detected in the duodenum of all fetuses. Gastrin component III was found to predominate in the antrum, whereas component II was quantitatively very important in the duodenum. Component I was detected in most extracts of both antrum and duodenum. These observations, together with those reported in animals, suggest that fetal gastrin is delivered to the blood, and that it may exert trophic functions in the fetus.

6624 FASTING AND POSTPRANDIAL SERUM GASTRIN IN NORMAL HUMAN NEONATES. (Eng.) Rodgers, B. M.; Dix, P. M.; Talbert, J. L.; McGuigan, J. E. (Box J-286, JHMHC, Gainesville, FL 32610). *J. Pediatr. Surg.* 13(1):13-16; 1978.

To elucidate information concerning the mechanisms involved in the initiation and regulation of the secretion of gastric acid in the neonate, the levels of gastrin in the blood of normal fasting newborn infants and the alterations in the serum gastrin levels elicited by normal feeding in the first 3 days of life were measured. In 13 infants for whom both maternal venous and umbilical cord venous samples were available, the average gastrin concentration was 92 pg/ml (range 17-183 pg/ml) in the maternal sample but 130 pg/ml (range 39-233 pg/ml) in the cord sample ($p<0.057$). In 22 fasting infants, the average peripheral venous gastrin concentration was 155 pg/ml (range 53-286 pg/ml), which was a significant ($p<0.006$) elevation over the 3- to 5-hr period since birth when the cord venous average gastrin value was 111 pg/ml (range 39-233 pg/ml). In 20 infants, the average fasting serum gastrin concentration was 151 pg/ml (range 31-286 pg/ml) prior to the first feeding, whereas it rose significantly ($p<0.034$) over the 60-hr period prior to the last hospital feeding (to 195 pg/ml, range 49-347 pg/ml). In comparing pre- and postprandial concentrations of serum gastrin, no significant differences were detected between breast- and bottle-fed infants. In 26 infants analyzed at the initial feeding and 14 analyzed at the final feeding, the increase in average serum gastrin concentration 30 min after feeding was not significant. These data support the hypothesis that the human neonate is capable of active gastrin secretion in the first few days of life. The absence of significant elevations in postprandial serum gastrin concentrations suggests the possibility of a relatively immature antral gastrin release mechanism in the newborn human infant.

6625 THE INFLUENCE OF GASTRIN ON PLASMA CALCIUM, BILE AND GASTRIC CALCIUM SECRETIONS IN THE RAT. (Eng.) Krishnamra, N.; Limlomwongse, L. (Dept. Physiology, Mahidol Univ., Bangkok 4, Thailand). *Proc. Soc. Exp. Biol. Med.* 158(1):40-44; 1978.

The influence of gastrin on Ca homeostasis was investigated in anesthetized female Fisher rats. When administered i.p., gastrin (50 μg/g) was found to lower the plasma Ca concentration in both intact rats ($p<0.01$) and thyroparathyroidectomized rats ($p<0.5$) but to exert no significant effect on the rates of urine Ca excretion in the intact rats. Thus, the hypocalcemic effect of gastrin is independent of calcitonin. In search of possible routes of Ca removal from the blood, both the Ca concentration in gastric juice and the total gastric Ca excretion were measured. Total gastric calcium excretion was increased from 14 ± 1.4 to 22 ± 2.4 μg/hr/100 g by the administration of gastrin. The increase in gastric Ca secretion and the hypocalcemic effect were abolished by concurrent administration of secretin (2 U). The bile volume and the Ca content in the bile secretion were not affected by gastrin. These findings were compatible with the hypothesis that the hypocalcemic effect of gastrin was partly caused by an increased Ca excretion into the gastrointestinal lumen.

6626 SELECTIVE RELEASE OF GASTRIC INHIBITORY POLYPEPTIDE BY INTRADUODENAL AMINO ACID PERFUSION IN MAN. (Eng.) Thomas, F. B.; Sinar, D.; Mazzaferri, E. L.; Cataland, S.; Mekhjian, H. S.; Caldwell, J. H.; *et al.* (Ohio State Univ. Hosp., 410 W. 10th Ave., Columbus, OH 43210). *Gastroenterology* 74(6):1261-1265; 1978.

To determine whether different groups of amino acids are more potent stimulators of gastric inhibitory polypeptide, 12 normal subjects received an intraduodenal perfusion of a mixed amino acid solution (158 mM) containing either methionine, phenylalanine, tryptophan, and valine (perfusate 1), or an amino acid solution containing arginine, histidine, isoleucine, leucine, lysine, and threonine (perfusate 2). Serum concentrations of gastric inhibitory polypeptide and insulin were significantly greater in the group receiving perfusate 2 ($p<0.001$). In contrast, after administration of amino acid perfusate 1, there was only a slight increase in serum gastric inhibitory polypeptide concentration, and insulin secretion increased only slightly. Mean trypsin and bilirubin outputs in the group receiving perfusate 1 were nearly 3 times greater than the outputs of the group receiving the other amino acid mixture. This study expands the importance of intraduodenal amino acid mixtures in stimulating secretion of gastric inhibitory polypeptide and insulin and quantitatively separates gastric inhibitory polypeptide release from release of hormones that stimulate pancreatic enzyme secretion, such as cholecystokinin.

6627 INHIBITORY ROLE OF THE DISTAL SMALL INTESTINE ON THE GASTRIC SECRETORY RESPONSE TO MEALS IN MAN. (Eng.) Clain, J. E.; Go, V. L. W.; Malagelada, J. R. (Mayo Clinic, Rochester, MN 55901). *Gastroenterology* 74(4):704-707; 1978.

The role of the distal small intestine in postprandial gastric function was investigated in six healthy subjects by diverting chyme from the intestine at a site 100 cm distal to the ligament of Treitz and comparing the results with those observed in the same subjects when chyme was exposed to the entire gut. Diversion of chyme significantly increased ($p<0.02$) gastric secretory volume and acid output during the first postprandial hour by an average of 78% and 70%, resp.; the increase in acid output during ileal diversion occurred during the first postprandial hour in every subject studied. The pH of the gastric contents in the diversion studies was consistently lower than that in the chyme exposed to the entire gut ($p<0.01$) between 20 min and 4 hr postprandially. The increased secretory volume and acid output in the first postprandial hour resulted in greater intragastric volume ($p<0.01$) and acid content ($p<0.05$) throughout the study period, whereas emptying of gastric contents and acid was similar in the control and diversion experiments. The results demonstrate that the distal small intestine has an inhibitory role in postprandial gastric secretion.

6628 CELLULAR MECHANISMS OF GASTRIC HYPERSECRETION IN PYLORUS-LIGATED RATS. (Eng.)

Mozsik, G.; Beck, Z.; Fuzesi, Z.; Kiss, J.; Nagy, L.; Palotai, Z.; *et al.* (Univ. Medical Sch., H-7643 Pecs, Hungary). *Acta Physiol. Scand.* (Suppl.):187-198; 1978.

The effects of epinephrine, theophylline, Degranol®, actinomycin D, tetracycline, ATP, ADP, AMP, cyclic 2'3'-AMP, and cyclic 3'5'-AMP (cAMP) on the gastric secretory responses of pylorus-ligated rats were studied to determine cellular mechanisms of gastric hypersecretion. The tissue levels of mucosal ATP, ADP, AMP, cAMP, lactate, and pyruvate were measured. Gastric hypersecretion in pylorus-ligated rats was inhibited dose-dependently by epinephrine, theophylline, Degranol®, actinomycin D, tetracycline, ADP, AMP, cyclic 2'3'-AMP, and cAMP. The plasma immunoreactive gastrin level did not change at different times (2, 4, 7, and 16 hr) after pylorus ligation. The tissue contents of ATP, cAMP, and lactate were significantly decreased within 2-4 hr after pylorus ligation ($p<0.001$), while the tissue levels of ADP and AMP significantly increased in that time ($p<0.001$). The increased tissue level of mucosal ADP was prevented by atropine, epinephrine, atropine plus theophylline, epinephrine plus theophylline, and histamine. The decreased mucosal level of cAMP that occurred within 4 hr after pylorus-ligation was elevated by theophylline, epinephrine, atropine plus theophylline, and epinephrine plus theophylline, but not by histamine or histamine plus theophylline. It is concluded that (1) an increase in DNA-dependent RNA synthesis, *de novo* DNA synthesis, and protein translation are needed for the development of gastric hypersecretion, (2) gastric hypersecretion in pylorus-ligated rats is an ATP-dependent process, and (3) the development of gastric hypersecretion is associated with an increase in ATP transformation to ADP and with a decrease in ATP transformation to cAMP. The blockage of gastric hypersecretion is therefore associated with a decrease in ATP transformation to ADP and with an increase in ATP transformation to cAMP. It is postulated that an extra- and intracellular feedback mechanism system exists between the ATP-ADP (membrane ATPase) system and the ATP-cAMP (adenylate cyclase) system of the gastric mucosa.

6629 EFFECT OF HISTAMINE H_1- AND H_2-RECEPTOR BLOCKADE ON CANINE GASTRIC ACID SECRETION.

(Eng.) Barbezat, G. O.; Bowey, F. S. B.; Kaplan, E. R.; Hickman, R. (Groote Schuur Hosp., Observatory, 7925, Cape Town, South Africa). *Am. J. Dig. Dis.* 23(3):222-224; 1978.

To unmask any H_1-receptor sites on parietal cells, a study was carried out to determine whether simultaneous administration of histamine H_1- and H_2-receptor antagonists had any greater effect on histamine-stimulated gastric secretion in the dog than did either of these substances given alone. Two dogs with gastric fistulae and Heidenhain pouches given only fluids for 18 hr received histamine (160 μg/kg/hr, i.v., by continuous infusion) throughout all tests. After 1.5 hr, a bolus injection of mepyramine (25 mg), metiamide (0.6 mg/kg), mepyramine and metiamide together (same doses), or saline (control) was given; six studies were done with each dose at least 72 hr apart. Secretions were collected every 15 min for 2 hr. Metiamide (an H_2-receptor antagonist) significantly inhibited histamine-stimulated gastric secretion in both the gastric fistula ($p<0.01$) and Heidenhain pouch ($p<0.001$). Mepyramine (an H_1-receptor antagonist) had no significant effect on gastric secretion either alone or in combination with metiamide. Two dogs with gastric fistulas received either mepyramine (25 mg, i.v., as a bolus followed by 12.5 mg over 250 min), metiamide (0.6 mg/kg/hr), mepyramine plus metiamide in the same doses, or saline. After 10 min, an i.v. histamine infusion was begun and the dose doubled every 40 min (10, 20, 40, 80, 160, and 320 μg/kg/hr). The dose-response curve of inhibition by metiamide and mepyramine was virtually superimposable on that for metiamide alone, confirming the results of the first study. The inhibition by metiamide appeared to be competitive. There is no evidence in these studies for the presence of histamine H_1-receptor sites on the gastric parietal cell.

6630 BIOAVAILABILITY OF CIMETIDINE IN MAN.

(Eng.) Walkenstein, S. S.; Dubb, J. W.; Randolph, W. C.; Westlake, W. J.; Stote, R. M.; Intoccia, A. P. (Smith Kline Corporation, 1500 Spring Garden St., Philadelphia, PA 19101). *Gastroenterology* 74(2):360-365; 1978.

The bioavailability of parenteral cimetidine was tested in 12 volunteers in a balanced three-way crossover study. Blood levels and urinary excretion were compared after i.m., i.v., and p.o. administration of 300 mg of cimetidine. The i.m. and i.v. routes were found to be virtually interchangeable for parenteral cimetidine. The p.o. liquid, although exhibiting a reduced area under the blood level curve as compared with the parenteral doses, nevertheless demonstrated equivalence with respect to the time the blood level remained above 0.5 μg/ml. In another group of 12 volunteers the 300-mg cimetidine tablet formulation was found to be bioequivalent to a 300-mg dose of p.o. liquid.

6631 EFFECT OF CIMETIDINE ON INTRINSIC FACTOR AND PEPSIN SECRETION IN MAN. (Eng.)

Binder, H. J.; Donaldson, R. M., Jr. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 74(2, Part 2):371-375; 1978.

The effect of two doses of cimetidine on betazole-stimulated gastric acid, pepsin, and intrinsic factor secretions was evaluated in 15 normal men. The p.o. administration of 300 mg of cimetidine resulted in significant decreases in betazole (1.5 mg/kg)-stimulated volume secretion ($p<0.05$), acid concentration ($p<0.001$), gastric acid output ($p<0.001$), and pepsin output ($p<0.01$), and it completely inhibited the increase in pepsin concentration, intrinsic factor concentration, and intrinsic factor output caused by betazole. A 200-mg cimetidine dose significantly inhibited gastric volume secretion ($p<0.05$), intrinsic factor output ($p<0.01$), gastric acid output ($p<0.02$), and pepsin output ($p<0.05$); the change in gastric acid output was not evident until 45 min after betazole administration, and the change in pepsin output was only seen during the last 45 min of observation. The diminished pepsin secretion observed with cimetidine may be merely a consequence of diminished acid secretion. Because this drug inhibits betazole-stimulated intrinsic factor secretion, and, in at least one previous study, pentagastrin-stimulated intrinsic factor secretion, it may be important to monitor the long-term effects of this agent on intrinsic factor production and on vitamin B_{12} absorption.

6632 EFFECT OF CIMETIDINE ON GASTRIC SECRETORY FUNCTION DURING STRESS.

(Eng.) Levine, B. A.; Sirinek, K. R.; Teegarden, D. K.; McLeod, C. G.; Pruitt, B. A. (U.S. Army Inst. Surgical Res., Fort Sam Houston, TX 78234). *J. Surg. Res.* 24(3): 178-181; 1978.

Cannulated female C-D rats were divided into two groups, stress (30 animals) and no stress (24 animals), each of which were subdivided equally into cimetidine-treated (20 mg/kg, i.p.) and control (saline-treated) subgroups to define the effect of cimetidine on gastric acid production in this awake model previously shown to produce acute, stress-related, gastric mucosal injury. Gastric secretions were collected for 4 hr in each group. Cimetidine significantly reduced the mean volume of gastric juice in nonstressed rats (from 0.72 ± 0.07 ml/hr in controls to 0.44 ± 0.03 ml/hr, $p<0.01$), but there was no significant difference in gastric output volume between control and cimetidine-treated stressed rats (0.32 ± 0.04 and 0.42 ± 0.04 ml/hr, resp.). Cimetidine significantly reduced gastric acid concentration in both the stressed (from 57.17 ± 6.56 to 17.29 ± 1.94 mEq/l, $p<0.01$, for controls and cimetidine-treated rats, resp.) and nonstressed groups (from 63.38 ± 3.68 to 50.80 ± 3.90 mEq/l, $p<0.05$). Cimetidine significantly reduced total acid output from that in control animals in both trials (from 47.22 ± 6.39 to 23.42 ± 2.82 μEq/hr, $p<0.01$, in unstressed rats, and from 18.54 ± 3.41 to 7.80 ± 3.37 μEq/hr, $p<0.01$, in stressed rats). Total acid output in the stressed control rats was significantly lower than in nonstressed controls ($p<0.01$), but unchanged from that seen in the unstressed cimetidine group. It is concluded that gastric acid concentration is more important than total acid output in formation of stress-related gastric mucosal injury and that cimetidine's protective role in stress is related to its ability to decrease gastric acid concentration.

6633 THE EFFECTS OF CIMETIDINE ON HEALING OF CHRONIC GASTRIC AND DUODENAL ULCERS IN DOGS.

(Eng.) Okabe, S.; Takeuchi, K.; Murata, T.; Urushidani, T. (Kyoto Coll. Pharmacy, 5 Goryo Nakauchi, Yamashina, Kyoto 607, Japan). *Am. J. Dig. Dis.* 23(2):166-168; 1978.

Studies were carried out to confirm previous reports that cimetidine accelerates healing of chronic gastric and duodenal ulcers. Gastric ulcers were produced in dogs by the subserosal injection of acetic acid solution and duodenal ulcers by topical application of acetic acid on the serosal surface of the duodenum. The dogs received cimetidine p.o. (450 mg/day) in three divided doses for 14 days. Although cimetidine had no significant effect on gastric ulcer healing, it produced a remarkable acceleration of healing of duodenal ulcers, compared with that in untreated controls ($p<0.001$). An apparent and relatively deep ulcer was observed in all 10 nontreated controls, whereas 4 of 10 treated dogs had a completely healed duodenal ulcer. These studies demonstrate that cimetidine treatment markedly accelerates duodenal ulcer healing.

6634 METIAMIDE: MORE THAN AN H_2-RECEPTOR ANTAGONIST.

(Eng.) Simay, D. A.; Peskin, G. W.; Saik, R. P. (Veterans Admin. Hosp., La Jolla Village Drive, San Diego, CA 92161). *Am. J. Dig. Dis.* 23(2):169-172; 1978.

To investigate the mechanism of action of metiamide on acid secretion, the effect of this drug on acid secretion and calcium uptake by the frog gastric mucosa was tested alone and in combination with histamine, pentagastrin, aminophylline, and dibutyrl cyclic AMP (db cAMP). Although metiamide (10^{-4} M) reduced the acid secretory rate stimulated by 5×10^{-5} M and 10^{-3} M histamine, the percent increase at the lower dose of histamine was not significantly different from that in the controls. This inhibition by metiamide of the lower dose of histamine was overcome by increasing the histamine concentration, suggesting that metiamide is an H_2-receptor antagonist with competitive dynamics. Pentagastrin, on a molar comparative basis, was a more potent stimulant of acid secretion than was histamine, causing a 178.9% increase at 2×10^{-6} M, suggesting that a separate receptor site is involved in pentagastrin-induced acid stimulation. Aminophylline (10^{-3} M) and db cAMP (10^{-3} M) stimulated acid secretion by 340.7% and 314.6%, resp. Metiamide inhibited acid secretion by both aminophylline (-12.1% at 10^{-3} M and -7.8% at 2×10^{-2} M aminophylline, not significant) and by db cAMP (-37.9% at 10^{-3} M, $p<0.05$), suggesting that metiamide is more than an H_2 blocker. Since these agents stimulate intracellularly, at a site beyond the adenylate cyclase membrane receptor complexes, it appears that metiamide also inhibits actively within the cell. Metiamide inhibition was overcome by markedly increasing the dose of db cAMP to 8×10^{-3} M. Calcium influx was increased by histamine, pentagastrin, and aminophylline administration to the same degree. Although db cAMP increased acid secretion, it did not increase calcium influx, suggesting that increased cellular activity alone is not the cause of calcium uptake. Metiamide, even while inhibiting acid secretion, caused a significant increase in Ca^{2+} uptake as well ($p<0.005$). Metiamide caused increases in stimulated Ca^{2+} uptake into the parietal cell. The results suggest that metiamide actively inhibits acid secretion at a point within the cell beyond the adenylate cyclase membrane receptor complexes. Its effect on calcium influx may be another mechanism of inhibition.

6635 CANCER RISK OF THE STOMACH RESECTED FOR ULCER. THE ROLE OF DUODENOGASTRIC REFLUX IN DIFFERENT GASTROENTERAL ANASTOMOSES.

(Ger.) Dahm, K.; Eichen, R.; Mitschke, H. (Abteilung Allgemeinchirurgie, Chirurgische Universitatsklinik, Martinistr. 52, D-2000 Hamburg 20, W. Germany). *Langenbecks Arch. Chir.* 344(2):71-82; 1977.

The effect of duodenogastric reflux on the carcinogenic activity of orally administered *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (NG, 120 mg/l in drinking water) was studied in male Wistar rats. Gastric resection with short-loop gastroenteric anastomosis (Billroth II) was prepared in 39 rats (group 1); this anastomosis provided for continuous duodenogastric reflux. Gastric resection with Roux-en-Y anastomosis was performed in 33 rats (group 2); this anastomosis caused the passage of bile and pancreatic juice into the jejunum without its coming into contact with the remaining part of the stomach. From the eighth postoperative week onward, the animals received drinking water with NG *ad libitum* and were sacrificed after 8.5 months. The incidence of tumors in the anastomosis region was 13/39 in group 1, 7/33 in group 2, and 5/27 in the nonoperated controls. The incidence of carcinomas was 11/39 in group 1, 7/33 in group 2, and 0/27 in the controls. Sarcomas were found in two animals in group 1 and in one control animal. Carcinomas of the anastomosis were found in 7/39 animals in group 1 and in 1/33 in group 2. Carcinomas of the small intestine were found in four and six animals in groups 1 and 2, resp. The findings indicate the substantial contribution of duodenogastric reflux to the development of carcinoma of the resected stomach.

6636 LYSINE ACETYLSALICYLATE INHIBITS THE PROTEIN SYNTHESIS IN THE RAT GASTRIC MUCOSA IN VIVO AND IN VITRO.

(Eng.) Pichl, J.; Mitznegg, P.; Subramanian, N.; Sprugel, W.; Domschke, W.; Estler, C. J. (Institut fur Pharmakologie und Toxikologie der Universitat Erlangen-Nurnberg, Universitatsstr. 22, D-8520 Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 25(1):52-54; 1978.

To elucidate a possible mechanism for the side-effects of lysine acetylsalicylate (LAS), the action of s.c.-administered LAS on protein synthesis of various organs was investigated in the rat, and to discriminate between direct and indirect actions of LAS, similar investigations on protein and nucleic acid synthesis were performed in isolated rat gastric mucosal tissue. Male Wistar rats that were starved for 24 hr received LAS (90-900 mg/kg, s.c.) and were killed 30 min or 2 hr later. Gastric mucosal protein synthesis was significantly ($p<0.001$) inhibited 30 min after a 90-mg/kg LAS dose, whereas the incorporation of ^{14}C-labeled precursors into tissue proteins in the duodenum and liver (997 ± 56 counts/min [cpm]/mg protein and 160 ± 21 cpm/mg protein, resp.) were not significantly different after the 900-mg/kg LAS dose from control values (1,014 ± 55 and 153 ± 13 cpm/mg protein, resp.). The incorporation of ^{14}C-labeled precursors into protein, ^{3}H-thymidine into DNA, and ^{14}C-orotic acid into RNA were studied in an *in vitro* preparation of gastric mucosa in the presence of 0.9-9 mg/ml LAS. LAS inhibited protein synthesis in a dose-dependent manner, but the values for ^{3}H-thymidine and ^{14}C-orotic acid incorporation were not different from control values. It is possible that the inhibition of translation by LAS could contribute to the potential ulcerogenic effect of acetylsalicylate and that parenteral administration of LAS would not protect the stomach from salicylate-induced side-effects.

6637 EFFECT OF n-METHYL-n'-NITRO-n-NITROSOGUANIDINE ON THE GASTRIC MUCOSAL BARRIER IN RATS.

(Eng.) Horowitz, I.; Toth, L. S.; Werther, J. L. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY 10029). *Am. J. Dig. Dis.* 23(6):510-512; 1978.

In the light of studies showing microscopic evidence of early inflammatory gastric mucosal damage after *N*-methyl-*N'*-nitro-*N*-nitrosoguanidine (MNNG) prior to the development of carcinoma, the gastric mucosal barrier to hydrogen ion (H$^+$) after MNNG administration in the rat stomach was studied. Increased H$^+$ back-diffusion was observed 3 hr after p.o. doses of 1 mg of MNNG over a 3-day period. MNNG in concentrations of 250 µg/ml, 167 µg/ml, 86 µg/ml, and 50 µg/ml in the presence of acid caused increased H$^+$ back-diffusion across the gastric mucosa within 1 hr. Gastric mucosal barrier disruption by MNNG may play a pathogenic role in gastric carcinogenesis.

SECRETION AND METABOLISM

Pancreas

6665 SECRETORY FUNCTION OF ISOLATED CANINE PANCREAS PERFUSED WITH FLUOROCARBON EMULSION. (Eng.) Kowalewski, K.; Kolodej, A. (Surgical-Medical Res. Inst., Univ. Alberta, Edmonton, Alberta, Canada). *Surg. Gynecol. Obstet.* 146(3): 375-378; 1978.

To assess the suitability of fluorocarbon emulsion for simultaneous perfusion of the canine stomach and pancreas, a gastroduodenopancreatic block was isolated that preserved the arterial circulation of the pancreas and was perfused *ex vivo* with a fluorocarbon emulsion oxygenated *in vitro* and containing a simulated physiologic protein-free solution. Pancreatic secretion was stimulated by secretin or cholecystokinin given as constant infusions over 5-6 hr into the arterial circulation. The response of the pancreas was essentially identical to that observed under *in vivo* conditions or during the perfusion of the isolated pancreas with homologous blood. Clear pancreatic secretion was collected for the entire 5-6 hr in response to both secretin and cholecystokinin. Gastric secretion was yellowish and contained, after about 3 hr of perfusion, a white fluorocarbon sediment. After 5 hr of perfusion, gastric corpus edema was evident, but at no time during 6 hr of perfusion was pancreatic edema noted. The volume, bicarbonate concentration, total protein concentration, and Cl^- concentration were significantly higher ($p<0.001$) in the secretin-induced secretion than in the cholecystokinin-induced secretion. The secretory viabilit of the canine pancreas is well-preserved under the conditions used in this study.

6666 COMPARISON OF THE BIOLOGICAL POTENCY OF A NEW SYNTHETIC PREPARATION OF SECRETIN WITH THAT OF NATURAL PORCINE SECRETIN IN THE DOG. (Eng.) Gyr, K.; Kayasseh, L.; Rittmann, W. W.; Girard, J.; Stalder, G. A. (Kantonsspital Basel, Switzerland). *Gut* 19(5):355-357; 1978.

The biological activity of a new synthetic secretin on exocrine pancreatic secretion was compared with that of natural porcine secretin in conscious dogs with chronic gastric and duodenal fistulae. The dose-response curves of the two preparations were parallel and nearly identical. The variances of the data were reduced when the parameters of pancreatic secretory response were corrected for body weight. Equimolar amounts of synthetic secretin and natural secretin produced responses of volume and bicarbonate secretion that were not significantly different. It is concluded that the new synthetic secretin is useful for clinical and research purposes.

SECRETION AND METABOLISM

Hepatobiliary Tract

6677 DETERMINANTS OF FASTING AND POSTPRANDIAL SERUM BILE ACID LEVELS IN HEALTHY MAN. (Eng.) LaRusso, N. F.; Hoffman, N. E.; Korman, M. G.; Hofmann, A. F.; Cowen, A. E. (Mayo Clinic and Mayo Foundation, Rochester, MN 55901). *Am. J. Dig. Dis.* 23(5):385-391; 1978.

The relationship between serum levels of cholic acid conjugates measured by radioimmunoassay, bile acid absorption, and hepatic clearance was studied to define the determinants of fasting and postprandial serum bile acids in healthy man. Acute or chronic interruption of the enterohepatic circulation caused a significant decrease in basal serum levels of cholyl conjugates in both dogs and humans ($p<0.05$), while liquid or solid meals caused a marked and reproducible increase in serum cholyl conjugates (humans studied only, $p<0.05$). A temporal correlation was demonstrated postprandially or after i.v. cholecystokinin (0.0625 U/kg/min for 30 min) between intestinal transit of bile acids and simultaneous changes in levels of serum cholyl conjugates. The plasma disappearance of i.v. injected radiolabeled cholylglycine was shown to be unaffected by serum levels of endogenous cholyl conjugates. These data are consistent with the interpretation that, in the presence of normal hepatic function, the major determinant of serum bile acids is their rate of intestinal absorption.

6678 ROLE OF ADENOSINE 3',5'-MONOPHOSPHATE (CYCLIC AMP) IN CANINE BILE-SALT-STIMULATED CHOLERESIS. (Eng.) Kaminski, D. L.; Ruwart, M. J.; Deshpande, Y. G. (St. Louis Univ. Sch. Medicine, St. Louis, MO). *Surg. Forum* 28:409-411; 1978.

To determine whether cyclic 3',5'-adenosine monophosphate (cAMP) functions as an intracellular mediator of bile salt-stimulated increases in hepatic bile flow, the effects of various doses of sodium taurocholate on bile cAMP secretion were evaluated in dogs with chronic gastric and biliary fistulas. Sodium taurocholate was infused for 90 min at doses of 9, 19, 37, 74, 149, or 298 μmol/min after the endogenous bile salt pool had been depleted by total diversion for 60 min. Progressive increases in sodium taurocholate dose caused progressive increases in bile volume, bile salt concentration, and bile salt output. There was a dose-related decrease in cAMP concentration and output that plateaued at 149 μmol/min (782 ± 146 pmol/ml and 44 ± 9 pmol/min, resp.); cAMP concentration and output at 9 μmol/min taurocholate were 6,508 ± 503 pmol/ml and 89 ± 18 pmol/min, resp. The results suggest that bile salt-stimulated canalicular bile flow is not mediated by cAMP.

6679 BINDING OF CHOLIC ACID TO SOLUBLE PROTEINS FROM RAT LIVER. (Eng.) McClelland, M. J.; Smallwood, R. A.; Hoffman, N. E.; Hoogenraad, N. J. (Austin Hosp., Heidelberg 3084, Australia). *FEBS Lett.* 82(2):255-258; 1977.

The binding of cholic acid to cytoplasmic proteins from the rat liver was examined. Most of the labeled bile acid was in the nuclei/membrane (31%) and supernatant (52%) fractions. In the supernatant fraction, the percentage of ^{3}H-cholic acid bound to protein as determined by ultrafiltration varied between 30% and 45%. Over 98% of the ^{3}H-cholic acid applied to the Sephadex G-75 column eluted as a single peak, at an elution volume identical to that of free ^{3}H-cholic acid. Thus, ^{3}H-cholic acid did not remain bound to the supernatant protein during gel filtration. In contrast, the ^{3}H-cholic acid did not become separated from protein during ultrafiltration using a membrane with a normal molecular weight retention limit of 50,000 daltons. Supernatant fractions from the column showed two areas that bound ^{14}C-cholic acid, the first fraction corresponding to a molecular weight of approximately 65,000 daltons and the second to 30,000-40,000 daltons. After the removal of albumin by diethylaminoethane (DEAE) chromatography, the two fractions that bound cholic acid were still present at the same molecular weight, showing that there were at least two proteins other than albumin that bind cholic acid. Proteolytic digestion with pronase completely destroyed all binding in these fractions, and the biochemical tests were positive for protein and negative for carbohydrate, suggesting that the binding species are protein, not glycoprotein.

6680 EFFECTS OF CHLORPROMAZINE HYDROCHLORIDE AND ITS METABOLITES ON Mg^{2+}- AND Na^{+},K^{+}-ATPase ACTIVITIES OF CANALICULAR-ENRICHED RAT LIVER PLASMA MEMBRANES. (Eng.) Samuels, A. M.; Carey, M. C. (Univ. Texas Health Science Center at Houston, P.O. Box 20708, Houston, TX 77025). *Gastroenterology* 74(6):1183-1190; 1978.

Because chlorpromazine hydrochloride has been reported to inhibit bile salt-dependent (BSD) and -independent (BSI) bile flow in a predictable fashion in primates and because a significant fraction of BSI bile flow is postulated to depend upon the activity of a canalicular membrane Na^{+},K^{+}-ATPase, the effects of chlorpromazine hydrochloride and its metabolites on the ATPase activities of canalicular-enriched rat liver plasma membranes were examined. Chlorpromazine inhibited the activities of both Mg^{2+}- and Na^{+},K^{+}-ATPases with a linear dose-response relationship between 10 and 100 μM. The inhibition of Na^{+},K^{+}-ATPase was pH dependent, showing a maximal inhibition at pH 7.8. Over the pH range 7.0 to 8.2, the inhibition was significantly reduced with the addition of glutathione ($p<0.05$) and was augmented under experimental conditions (UV irradiation and peroxidase-H$_2$O$_2$, by from 41% to 98% and from 38% to 80%, resp.) that promote the formation of the chlorpromazine semiquinone free radical. The 7-hydroxychlorpromazine metabolite was as active an inhibitor as the parent drug; however, two sulfoxide metabolites, chlorpromazine sulfoxide and 7-hydroxychlorpromazine sulfoxide, were less effective inhibitors of Na^{+},K^{+}-ATPase. These data are consistent with the hypothesis that chlorpromazine cholestasis may be a result of a direct toxic effect on the ATPase activities of hepatic canalicular membranes. The results further suggest that if chlorpromazine cholestasis occurs through an interaction with canalicular membrane ATPases, the degree of cholestasis may well be influenced by the extent of the conversion of the drug to its more active (free radical) or minimally active (sulfoxide) metabolites and by the local environment (pH and glutathione concentration) of the canalicular membrane.

6681 THE EFFECT OF S-ADENOSYL-L-METHIONINE ON ETHYNYLESTRADIOL-INDUCED IMPAIRMENT OF BILE FLOW IN FEMALE RATS. (Eng.) Stramentinoli, G.; Gualano, M.; Di Padova, C. (BioResearch Co., I-20060 Liscate, Milano, Italy). *Experientia* 33 (10):1361-1362; 1978.

Because S-adenosyl-L-methionine (SAMe) is the methylating agent in the enzymatic methylation by catechol-*O*-methyl transferase (CMT), the effect of SAMe administration on the bile flow reduction caused by ethynylestradiol (EE) was examined in female Sprague-Dawley rats. Five groups of animals were treated as follows: group 1, 2.5 mg/kg EE for 3 days by gastric intubation; group 2, EE as before plus 10 mg/kg SAMe i.m. t.i.d. for 3 days; group 3, same as group 2 except 25 mg/kg SAMe; group 4, solvent for EE (control); and group 5, same as group 4 plus 25 mg/kg SAMe on same schedule as group 3 (control). Bile flow and bile salt concentration were determined after a 12-hr fast. Bile flow was slower in EE-treated rats than in either group of controls ($p<0.05$). Either dose of SAMe given with EE was capable of restoring bile flow to control values. The bile salt concentration was higher in EE-treated animals than in any other group ($p<0.01$), although the amount excreted did not change significantly. When the bile salt independent fraction of bile was calculated for the groups, a significant difference was observed between the value for EE-treated rats (0.49 µl/min/g liver) and that for controls (1.30 µl/min/g liver, $p<0.01$) and between the value for EE-treated rats and the values for rats treated with 10 mg/kg SAMe (1.15 µl/min/g liver) and 25 mg/kg SAMe (1.40 µl/min/g liver, $p<0.01$ for both). If bile flow during the first 30 min of collection is considered to be 100%, then the bile salt-independent fraction of bile water represents 66% of total bile flow in the controls, 39.2% in EE-treated rats, and 60 and 68%, resp., in rats treated with 10 or 25 mg/kg SAMe in addition to EE. These results are in good agreement with the hypothesis that the reduction of bile flow after EE administration may be associated with alteration of the canalicular water secretion into bile independently of the secretion of bile salts. It is postulated that SAMe exerts its effects by reducing the binding of methylated steroids to microsomal proteins in rat liver, perhaps by favoring the enzymatic methylation of the catechol estrogens by CMT.

6682 INDEPENDENCE OF BILE ACID AND OUABAIN HEPATIC UPTAKE: STUDIES IN THE NEWBORN RAT.

(Eng.) Klaassen, C. D. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Proc. Soc. Exp. Biol. Med.* 157(1):66-69; 1978.

Studies were carried out in newborn and adult Sprague-Dawley rats to determine whether bile acids are transported by the same process that transports neutral organic compounds or steroids in the liver. The plasma taurocholic acid concentration 15 min after the i.v. administration of taurocholic acid (30 mg/kg) was approximately 6 µg/ml in rats 20 days of age and older, whereas the concentration was more than fourfold higher in 10-day-old rats. There was a marked decrease in the plasma concentration of taurocholic acid 15 min after its administration as the rats increased in age from 5 to 20 days, and the plasma concentration in the 5-day-old rats was significantly lower than that in the 10-day-old rats ($p<0.05$). The taurocholic acid concentration was measured in the plasma, liver, and intestine at 2, 5, 10, 20, and 30 min after its administration to 7- and 39-day-old rats. The plasma level of taurocholic acid was already significantly higher ($p<0.05$) in the 7-day-old than in the 39-day-old rats at 2 min after administration, suggesting a larger volume distribution. The difference between the newborn and adult became greater at the longer time intervals. The taurocholate concentration in the liver of the newborn rat was significantly higher than that in the adult at 5 min after administration and at all times thereafter ($p<0.05$). The ratio of hepatic taurocholic acid concentration to its concentration in the plasma in the newborn rat was significantly lower ($p<0.05$) than in the older animals at the 2-min interval but was similar to the adult rat at all times thereafter. The newborn rats excreted significantly less ($p<0.05$) taurocholate into the intestine than the adults at all times after administration except at 30 min. The slower plasma disappearance and biliary excretion of taurocholic acid in the newborn appears to be due largely to a less efficient transfer of taurocholic acid from the liver into the bile, while the liver/plasma concentration ratio of taurocholate in the newborn is similar to that in the adult. The fact that ouabain cannot be taken up and concentrated in the newborn rat liver suggests that taurocholic acid and ouabain are transported into the hepatocyte by different systems.

6683 INFLUENCE OF PENTAGASTRIN, CHOLECYSTOKININ AND CERULEIN ON BILE PRODUCTION IN THE RAT.

(Fre.) Dangoumau, J.; Balabaud, C.; Bussiere-Leboeuf, C.; Dallet-Duverge, F.; Noel, M. (Laboratoire de Pharmacologie, Universite de Bordeaux II, 3, place de la Victoire, F 33000 Bordeaux, France). *J. Pharmacol. (Paris)* 8(2):197-204; 1977.

The effects of pentagastrin, cholecystokinin, and cerulein (all possessing the same C-terminal tetrapeptide) on bile production were compared in 60 anesthetized male Wistar rats with acute biliary fistulas. When pentagastrin was perfused into the hepatic artery or portal vein (10 µg/100 g body weight/hr for 1 hr), there was no effect on bile flow. When cholecystokinin was perfused (1 U/100 g body weight/hr, for 1 hr) into the jugular vein, there was an average increase of bile flow of 23% (from 6.73 ± 1.14 to 8.28 µl/100 g body weight/min). The concentration and, to a lesser degree, the output of bile salts decreased significantly ($p<0.02$). The concentration of bicarbonates did not change, but their output increased significantly ($p<0.001$). Erythritol clearance increased significantly from 7.16 ± 1.19 to 8.2 ± 0.94 µl/100 g/min, $p<0.01$, and the bile to plasma erythritol concentration ratio decreased significantly from 1.03 ± 0.01 to 0.97 ± 0.03 ($p<0.02$). A cerulein perfusion into the jugular (2 µg/100 g body weight/hr, for 1 hr) caused an average increase of bile flow of 19% (from 7.62 ± 0.98 to 9.11 ± 1.70 µl/100 g body weight/min). The concentration and output of bile salts decreased significantly ($p<0.001$) and the bicarbonate output and concentration increased significantly ($p<0.001$). These results suggest that pentagastrin, cholecystokinin, and cerulein have different effects on bile production in rats, in spite of their similar structure. The rat is insensitive to the hormone pentagastrin. Although cerulein increases the bile flow, its effect is very variable. Cholecystokinin stimulates ductular secretion of bile, but it also may inhibit the eventual ductular reabsorption of water, Na^+, and Cl^- and increase ductular permeability to erythritol.

6684 INFLUENCE OF SECRETIN ON BILE PRODUCTION IN THE RAT. (Fre.) Balabaud, C.; Noel, M.; Dangoumau, J. (Laboratoire de Pharmacologie, Universite de Bordeaux II, 3, place de la Victoire, F 33000 Bordeaux, France). *J. Pharmacol. (Paris)* 8(2):191-196; 1977.

The effect of secretin on the rat was studied to clarify its physiological impact on bile production in this species. Anesthetized male Wistar rats were perfused for 30 min with a solution of NaCl (9 g/l) with the addition of secretin for 60 min (20 U/kg body weight/hr). In seven of eight rats perfused into the hepatic artery, the average bile flow increased significantly ($p<0.001$) from a basal value of 5.84 ± 0.64 to 6.81 ± 1.12 µl/100 g/min when secretin was administered. The concentration and biliary flow of bicarbonates also increased significantly (from 0.175 ± 0.019 to 0.256 ± 0.060 µEq/100 g/min, $p<0.01$). When secretin was perfused into the portal vein, bile flow rose significantly in seven of eight rats (from 5.46 ± 0.94 to 6.51 ± 0.80 µl/100 g/min); the concentration of bicarbonates essentially did not change, but their output rose markedly. When ^{14}C-erythrol was injected into the penial vein of seven rats, its clearance increased from 6.48 ± 0.76 to 6.79 ± 1.20 µl/100 g/min during the secretin administration; the rise was not significant. When secretin was infused into the jugular vein, it failed to induce an increase in bile flow or bicarbonate output. These results show that secretin has a very weak choleretic effect in the rat as compared to man or dog, even when given in very high doses.

6685 EFFECTS OF PORTACAVAL SHUNT ON BILE ACID METABOLISM IN DOGS. (Eng.) Kuo, J.; Pertsemlidis, D.; Panveliwalla, D. (Mount Sinai Sch. Medicine, City Univ. New York, New York, NY). *Surg. Forum* 28:402-403; 1977.

To investigate how the shunting of bile acid-rich portal blood into the systemic periphery affects hepatic synthesis and pool size of bile acids and to validate the isotope dilution method of Lindstedt, studies were performed before (control) and after end-to-side portacaval shunt was carried out in 12 female adult mongrel dogs. Studies were done in the steady state, i.e., in the absence of liver failure and with the maintenance of constant body weight. Cholecystokinin-stimulated bile was collected for 6-7 days after i.v. infusion of 10-15 µCi of ^{14}C-cholic or ^{14}C-chenodeoxycholic acid. The pool size of cholic acid was significantly decreased after shunt (from 1,720 ± 610 to 524 ± 134 mg, $p<0.001$). The synthesis of cholic acid declined significantly after shunt (from 701 ± 300 to 351 ± 137 mg/day, $p<0.01$). The fractional turnover rate for cholic acid increased significantly after shunt (from 0.421 ± 0.118/day to 0.705 ± 0.426/day, $p<0.001$). Cholic acid made up 80%, deoxycholic acid 18%, and chenodeoxycholic acid 2% of the total bile acid mass. In two control and two shunted dogs, a known dose of ^{14}C-24-cholic acid was given i.v. 12 hr prior to sacrifice, and postmortem chemical measurement of the cholic acid pool (percentage recovery of isotope and bile acid mass in the gallbladder, liver, and intestine) was compared with pool size estimates in premortem isoto dilution studies. The isotope dilution method underestimated pool size by 27-31% in three of the four dogs. Postmortem isotope recovery was more than 90%. It is concluded that the shunted liver is unable to accelerate bile acid synthesis in response to the increased fractional turnover and presumed diminution of bile acid return. The decline in hepatic bile synthesis may be due to hepatocyte dysfunction. The isotope dilution method appears to underestimate bile acid pool size.

6686 CHOLESTEROL KINETICS FOLLOWING PORTACAVAL SHUNT IN DOGS. (Eng.) Coyle, J. J.; Guzman, I. J.; Varco, R. L.; Buchwald, H. (Univ. Minnesota Medical Sch., Minneapolis, MN). *Surg. Forum* 28:404-405; 1977.

Because portacaval shunt (PCS) has been proposed as a therapy for type II homozygous hypercholesterolemia, a study was undertaken to determine cholesterol (CH) kinetics (pool size and production rate) in the dog 1 yr after PCS. Three mongrel dogs that had undergone end-to-end PCS 44 weeks previously and five control dogs, all of which were in CH steady state (stable plasma CH levels and stable weights) were given i.v. injections of ^{14}-CH, and the plasma CH specific activity was determined biweekly for 5 weeks. Analysis of the data permitted the determination of both the rapidly and slowly miscible CH pool sizes and of the CH production rate. There were no significant differences in these three parameters between the control and PCS animals. The only significant difference ($p<0.01$) between the two groups was that the plasma cholesterol level of the controls (157 mg/100 ml) exceeded that of the PCS animals (76 mg/100 ml). Three explanations for the hypocholesterolemic mechanism of PCS in the dog are suggested: (1) changes may occur in CH transport, a decrease may occur in lipoprotein synthesis, or an increase may occur in lipoprotein catabolism, (2) shifts may occur in the CH pool distribution that were not detected in this isotopic model, or (3) shifts may occur in the CH pool between the compartments of the rapidly miscible pool that are undetectable in measurements of the total pool.

6687 DECREASED CHOLESTEROL AND FATTY ACID SYNTHESIS FOLLOWING PORTACAVAL SHUNT. (Eng.) James, J. H.; Soeters, P. B.; Escourrou, J.; Fischer, J. E. (Massachusetts General Hosp., Boston, MA). *Surg. Forum* 28:397-399; 1977.

To examine the mechanism whereby portacaval anastomosis (PCA) reduces plasma levels of triglycerides and cholesterol (C), *in vivo* hepatic lipid synthesis was measured in the rat after PCA. PCA was performed in 32 female Sprague-Dawley rats and sham operation in 32 others; 2 weeks later, hormonal and absorptive effects were synchronized by a feeding schedule that lasted 2 weeks. On the day of the experiment, half of each group was fed and half was starved, each animal received $^{3}H_2O$ i.v., and animals were killed 0.5, 1, 2, or 4 hr after injection. Homogenized organs were examined for ^{3}H-labeled fatty acids (FA) and C. A significant reduction ($p<0.01$) in FA synthesis after PCA was seen at all times after injection of ^3H_2O in both fed and starved rats. FA synthesis was markedly stimulated by feeding, but this stimulation was reduced by PCA. Hepatic synthesis of C was significantly decreased ($p<0.01$) by PCA in the starved rats, but a significant reduction in the fed group with PCA was seen only at the 4-hr point ($p<0.01$). These results suggest that the diversion of portal flow from the liver by PCA leads to reduced hepatic substrate supply and hence to reduced FA synthesis. The reduced substrate supply may not be limiting for the synthesis of C after PCA, and other regulatory factors may be more important.

6688 EFFECT OF SUCROSE ON LIPOGENESIS OF RATS CHRONICALLY TREATED WITH ETHANOL. (Eng.)

Pennington, S. N.; Barakat, H. A.; Dohm, G. L.; Smith, C. P. (Sch. Medicine, East Carolina Univ., Greenville, NC 27834). *Experientia* 34(5):564-565; 1978.

To find a method of ethanol dosing that would allow normal weight gain, the effect of sucrose on lipogenesis was studied in male, alcohol-fed Holtzman rats. Fifteen animals received ethanol (4 g/kg/day) as a 50/50 (volume/volume) solution in normal saline by stomach tube, and 15 controls received saline alone. In another group, 15 animals received a mixture of 25% sucrose and 25% ethanol in water (weight/volume/volume) as their only source of fluid, and an equal number of controls received a 25% sucrose solution. At the end of 28 and 56 days, the livers and epididymal fat pads were removed and analyzed for several lipogenic enzymes in six animals from each of the four groups. Adipose tissue glucose-6-phosphate dehydrogenase (G6PDH), fatty acid synthetase (FAS), and citrate cleavage enzyme (CCE) activities were significantly elevated ($p<0.05$) after 28 days of ethanol treatment, in comparison with the levels in saline-treated controls; malic enzyme (ME) was also raised, but not significantly. Liver enzyme levels were unaffected, and only liver CCE was significantly elevated after 56 days of ethanol treatment. Ethanol plus sucrose treatment caused significant decreases in adipose and liver ME activity at 28 days, compared with those in animals treated with sucrose alone ($p<0.05$). At 56 days, sucrose plus ethanol treatment caused significant decreases ($p<0.05$) in all tissues of all enzymes studied except liver CCE. Sucrose alone caused 2- to 10-fold increases in all enzymes in all tissues, relative to saline-treated animals. The results show that, depending on whether sucrose is used in the control, ethanol can increase or decrease the activities of lipogenic enzymes, particularly in rat adipose tissue.

6689 EFFECT OF EXPERIMENTAL BILIARY OBSTRUCTION ON THE PLASMA AND ERYTHROCYTE LIPIDS OF THE GUINEA PIG AND ON PLASMA PHOSPHATIDYLCHOLINE-CHOLESTEROL ACYLTRANSFERASE ACTIVITY. (Eng.)

Owen, J. S.; Bruckdorfer, K. R.; McIntyre, N. (Royal Free Hosp. Sch. Medicine, 8 Hunter St., London WC1N 1BP, England). *Biochem. Soc. Trans.* 5(5):1330-1333; 1977.

The guinea pig was assessed as an experimental model to establish whether the increases in plasma phospholipid and unesterified cholesterol and the changes in erythrocyte lipid content and morphology that are seen in human biliary obstruction occur in this animal. Double ligation or sham-operation was performed on the common bile ducts of male Dunkley-Hartley guinea pigs, and animals were killed 2, 5, or 12 days later. There was also a group of nonoperated controls. The concentrations of plasma bile acids were significantly higher in operated animals at all three times compared with nonoperated controls ($p<0.001$): 295 ± 120, 328 ± 119, and 796 ± 56 nM at 2, 5, and 12 days, resp., compared with 14 ± 6 nM in controls. Total phospholipid and unesterified cholesterol levels were significantly higher ($p<0.01$) in operated animals only at 12 days (0.74 ± 0.16 mM versus 0.43 ± 0.02 mM in controls and 0.34 ± 0.02 mM versus 0.19 ± 0.03 mM in controls, resp.). The percentage of unesterified cholesterol was significantly higher in operated animals (32 ± 5, 30 ± 2, and 47 ± 15% at 2, 5, and 12 days, resp.; $p<0.05$, $p<0.01$, and $p<0.05$, resp.) compared with controls (23 ± 1%). The phosphatidylcholine-cholesterol acyltransferase activity in operated animals did not decrease compared with sham-ligated controls, although one of two 12-day postoperated animals did show a marked decrease. The RBC of the 12-day and two of the four 5-day postoperated animals showed abnormal morphology and appeared similar to the spur cells of human liver disease; these animals were also the only ones to show an increased RBC cholesterol/phospholipid ratio compared with controls, although in three of the four animals the increase was modest (6-10%). The phospholipid content and the composition of the individual phospholipids was not altered. No differences in osmotic fragility of RBC from operated and sham-operated animals was found. The lack of marked increases in plasma phospholipid or unesterified cholesterol concentrations might be due to only minor biliary regurgitation of phospholipid into the plasma owing to the presence of a distensible gallbladder. Ligation of the bile duct above the gallbladder in the guinea pig might therefore prove a more suitable model.

6690 DISSOCIATION BETWEEN RATE OF HEPATIC LIPOPROTEIN SECRETION AND HEPATOCYTE MICROTUBULE CONTENT. (Eng.)

Reaven, E. P.; Reaven, G. M. (Stanford Univ. Sch. Medicine, Palo Alto, CA 94304). *J. Cell Biol.* 77(3):735-742; 1978.

To further define the relationship between microtubules and hepatic very low density lipoprotein (VLDL) secretion, experiments were carried out to see if changes in hepatic VLDL secretion are associated with changes in hepatocyte microtubule or tubulin content. In acute experiments, VLDL secretion was increased by perfusion of isolated rat livers for 2 hr with varying concentrations of free fatty acids (FFA). Hepatic VLDL triglyceride (TG) secretion at perfusate FFA levels of 0.7 μEq/ml was threefold greater ($p<0.01$) than when livers were perfused without added FFA. However, no differences were observed in the content of microtubules in these livers: specifically, microtubules occupied 0.029% of hepatocyte cytoplasm in livers perfused without FFA and 0.030% of cytoplasm in livers perfused with FFA. In chronic experiments, rats were fed for 1 week with either standard rat chow or a hyperlipemic (sucrose/lard) diet. With the experimental diet, plasma triglyceride levels increased threefold over controls, and liver VLDL-TG production, as determined by [^{3}H]glycerol turnover studies, was 55% greater ($p<0.01$) than controls. However, microtubules occupied 0.027% of the cytoplasm of hepatocyte cytoplasm whether rats were on standard or hyperlipemic diets. Furthermore, the tubulin content of isolated hepatocytes did change, and represented 1% of hepatocyte soluble protein, irrespective of diet. These results suggest that increases in hepatic VLDL secretion can occur without any demonstrable change in hepatocyte assembled microtubule or tubulin content and raise questions as to the role played by microtubules in hepatic VLDL secretion.

6691 EFFECT OF PORTACAVAL SHUNT ON LIPOPROTEINS AND AMINO ACIDS IN MONKEYS.

(Eng.) Casali, R. E.; Nelson, C. A.; Read, R. C.; Campbell, G. S.; Morris, M. D. (Arkansas Sch. Medicine, Little Rock, AR). *Surg. Forum* 28:400-401; 1977.

To examine the effects of end-to-side portasystemic shunts (PCS) on total serum levels of cholesterol (C), triglycerides (T), α-lipoproteins (HDL), β-lipoproteins (LDL), and the ratio of branched-chain and aromatic amino acids (BCA/AA) in hypercholesterolemic cynomolgus monkeys, 13 monkeys were fed a diet containing 0.3 mg of C/kg/cal and 45% total calories as fat for 2 months. Then they were randomly distributed for sham operations or PCS after which serum levels of C, T, HDL, LDL, and BCA/AA were measured bimonthly. All of the animals survived and none has shown clinical signs of encephalopathy in 10 months of observation. There was no difference in total C, T, or LDL levels between the two groups. However, HDL levels were higher in animals with sham operations (33 mg/100 ml) than in animals with PCS (27 mg/100 ml), and the BCA/AA ratio was significantly lower ($p<0.001$) in animals with PCS (2.2 mg/100 ml, range 1.8-2.8 mg/100 ml) than in sham-operated animals (3.96 mg/100 ml, range 2.9-7.4 mg/100 ml). Each animal maintained a relatively constant BCA/AA ratio. In cynomolgus monkeys, PCS does not affect total serum levels of C, T, or LDL in dietary-induced hypercholesterolemia. The reduced ratio of BCA/AA in PCS was produced by a relative increase in AA with BCA remaining constant.

6692 DECREASE IN CHOLESTEROL AND PHOSPHOLIPID SECRETION INTO BILE INDUCED BY CHOLEPHILIC DYES IN HAMSTERS.

(Fre.) Dumont, M.; Erlinger, S. (Hopital Beaujon, F 92118 Clichy Cedex, France). *Gastroenterol. Clin. Biol.* 1(11):891-896; 1977.

The effect of cholephilic anionic dyes on the biliary lipid secretion of anesthetized male golden hamsters was studied. Bile flow and bile salt outputs remained unchanged when BSP (76-80 nmol/min/100 g), phenol-3,6-dibromophthalein disulfonate (DBSP, 90-93 nmol/min/100 g), and indocyanine green (ICG, 23-27 nmol/min/100 g) were added to a perfusion of sodium taurocholate into the common bile duct. Phospholipids were significantly decreased by BSP (57.6%, $p<0.01$), DBSP (47.2%, $p<0.05$), and ICG (26.6%, $p<0.02$). Cholesterol output was also decreased by BSP (70.9%, $p<0.01$), DBSP (60.9%, $p<0.05$), and ICG (44.7%, not significant). Similarly, the cholesterol saturation index of bile was significantly decreased by BSP ($p<0.01$) and DBSP ($p<0.05$) but not significantly decreased by ICG. The decreases were registered within 30 min of adding the dyes to the perfusate, and values started to rise again as soon as the dyes were stopped. These results suggest that cholephilic anionic dyes interfere with phospholipid and cholesterol secretion into the bile, possibly by altering micelle formation, and not by preventing their synthesis.

6693 LACK OF ENTEROHEPATIC CIRCULATION OF INTACT BILIARY PHOSPHATIDYLCHOLINE IN THE RAT.

(Eng.) Larsson, B.; Nilsson, A. (Medicinsk kemiska institutionen 4, Box 750, 220 07 Lund 7, Sweden). *Scand. J. Gastroenterol.* 13(3):273-275; 1978.

To determine the extent to which biliary phosphatidylcholine recirculates in bile, *in vivo*-labeled bile was obtained by injecting male white rats i.v. or i.p. with ^{14}C-palmitic acid or ^{3}H-palmitic acid mixed with an equimolar amount of KOH and 50-100 mg fat-free bovine serum albumin following bile duct cannulation. The infused radioactivity was recovered in phosphatidylcholine, chloroform-soluble compounds, and water:methanol-soluble compounds from bile collected over 6 hr, whether the injected compound was ^{14}C-palmitic acid (49.3 ± 5.5, 63.1 ± 5.4, and 36.9 ± 5.4%, resp.) or ^{3}H-palmitic acid (25.6 ± 7.7, 51.0 ± 17.4, and 49.0 ± 17.4%, resp.). When ^{3}H- and ^{14}C-labeled bile was infused intraduodenally into other rats prepared with bile fistulas, the average recovery of radioactivity in bile over 6 hr was 18.5 ± 8.8 and 8.4 ± 4.3%, resp., and the radioactivity recovered as phosphatidylcholine was 1.74 ± 0.80 and 0.10 ± 0.03%, resp. When ^{3}H-taurocholate was infused simultaneously with ^{14}C-bile, 68 ± 5.0% of the infused ^{3}H was recovered over 6 hr. Thus, the low recovery of biliary phosphatidylcholine was not due to disturbed enterohepatic circulation in the bile fistula rats. When ^{3}H-dipalmitoyl phosphatidylcholine was infused with the ^{14}C-bile, <0.2% of the infused ^{3}H was recovered as biliary phosphatidylcholine. Since the distribution of radioactivity in the labeled phosphatidylcholine molecules was not determined in the experiments with palmitic acid, the fate of the injected label cannot be stated. Hence, these results do not exclude a recirculation of phosphatidylcholine by a deacylation-reacylation cycle. The results do indicate that there is no significant enterohepatic circulation of intact biliary phosphatidylcholine. This conclusion is at variance with previously published results of other authors.

6694 PROTEIN COMPOSITION OF RAT BILE. (Eng.) Kakis, G.; Yousef, I. M. (Dept. Pathology, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Can. J. Biochem.* 56(5):287-290; 1978.

To determine whether there is an association between biliary lipids and peptides or proteins, bile proteins were quantitated and identified in rats during the 48 hr following bile duct cannulation. Both total biliary protein secretion and the protein polypeptide profiles remained constant throughout the 48-hr period. The bile acids secreted in the first 5 hr contained 3-30% deoxycholic acid, ursodeoxycholic acid, and hyodeoxycholic acid. These bile acids disappeared thereafter, and the bile acids secreted consisted mainly of cholic acid and chenodeoxycholic acid. α-Muricholic, β-muricholic, and 3α,6-ketocholanic acid secretion continued throughout the experiment but was highest during the first 5 hr. Non-sodium dodecyl sulfate polyacrylamide gel electrophoresis of the biliary proteins secreted at various times showed seven major bands accounting for 90% of the total protein secreted. Sodium dodecyl sulfate polyacrylamide gel electrophoresis showed about 25 polypeptide bands, their molecular weights ranging from $12\text{-}140 \times 10^3$. These results show that protein secretion and protein polypeptide profiles remain constant, while bile acid secretion fluctuates markedly in both quantity and composition. It is concluded that biliary protein secretion is probably not related to the biliary secretion of bile acids.

6695 THE EFFECT OF DIETARY PROTEIN DEFICIENCY ON ALBUMIN SYNTHESIS AND ON THE CONCENTRATION OF ACTIVE ALBUMIN MESSENGER RIBONUCLEIC ACID IN RAT LIVER. (Eng.) Pain, V. M.; Clemens, M. J.; Garlick, P. J. (London Sch. Hygiene and Tropical Medicine, London WC1E 7HT, England). *Biochem. J.* 172(1):129-135; 1978.

A messenger-dependent rabbit reticulocyte lysate system was used to test the hypothesis that the decrease of liver albumin synthesis in humans and rats on protein-deficient diets is due to decreased availability of translatable messenger RNA (mRNA). COBS Wistar rats were divided into four groups according to the following dietary regimens: group I, complete; group II, protein-free for 9 days; group III, protein-free for 2 days; and group IV, protein-free for 9 days, then refed for 2 days with complete diet. By measuring the accumulation of i.v.-injected radioactive leucine in albumin immunoprecipitates, the proportion of albumin synthesis to total hepatic protein synthesis *in vivo* was established at 15%; the values for each of the groups were 14.6 ± 0.50, 7.98 ± 0.62, 8.34 ± 0.52, and 12.7 ± 0.65, for groups I, II, III, and IV, resp. ($p<0.001$ for II and III compared with I; $p<0.05$ for IV compared with I; $p<0.001$ for IV compared with II). In the messenger-dependent reticulocyte lysate system and also in the same lysate without nuclease pretreatment, synthesis of albumin and synthesis of total protein were measured as functions of the amount of total cytoplasmic hepatic mRNA added to the mixtures (up to 4 μg/50 μl). In the untreated system, the little or no response to added mRNA was attributed to the extensive protein synthesis on endogenous mRNA. In the messenger-dependent system, results were expressed in terms of radioactivity incorporated into albumin and into total protein per μg of RNA added; only the group II results were significantly different ($p<0.005$) from the controls (group I). Polyacrylamide gel analysis revealed that almost all of the radioactivity in the immunoprecipitate comigrated with an albumin marker. In liver samples from group II rats, the concentration of albumin RNA was half that found in samples from the group I rats. In group IV samples, however, increases in albumin mRNA levels produced by refeeding were not statistically significant; this and other discrepancies between the *in vivo* and *in vitro* results are discussed. The results suggest that the availability of specific mRNA species may well be responsible for the nutritional regulation of albumin synthesis, but it is not known whether the reduced availability of translatable mRNA is a primary effect of protein deprivation or a secondary effect at the level of translation or secretion.

6696 THE EFFECT OF PROSTHETIC GALLSTONES ON TOTAL BILE ACID POOL SIZE IN DOGS. (Eng.) Thurston, O. G.; McDougall, R. M.; Walker, K. (Dept. Surgery, Univ. Alberta, Edmonton, Alberta, Canada). *Surg. Gynecol. Obstet.* 146(6):911-913; 1978.

To determine whether the small bile acid pool characteristic of patients with cholesterol gallstones is responsible for gallstone formation or whether the reverse is true, the effect of prosthetic gallstones on total bile acid pool size was studied in dogs. The pool size was determined (by injecting ^{14}C-cholic acid) before and 28 days after the implantation of one or more polymeric silicone and/or glass spherical prostheses. The total bile acid pool size was reduced in 9 of 10 dogs after the implantation of the prostheses. The mean pool size fell from 4.25 ± 0.44 g to 2.91 ± 0.31 g ($p<0.01$). Sham cholecystectomy without prosthesis implantation also produced a small decrease in bile acid pool size but was significantly less than the decrease noted with prosthetic stones ($p<0.05$). Bile acid ratios (of cholic acid, chenodeoxycholic acid, and deoxycholic acid) did not change after implantation. These findings suggest that the small total bile acid pool size in patients with cholesterol stones is a phenomenon secondary to the pathologic state of the gallbladder.

6697 VITAMIN C AND GALLSTONE FORMATION: A PRELIMINARY REPORT. (Eng.) Jenkins, S. A. (Pye Res. Center, Walnut Tree Manor, Haughley Green, Suffolk IP14 3RS, England). *Experientia* 33(12):1616-1617; 1977.

An experiment was conducted to examine the relationships between vitamin C and gallstone formation. Male Dunkin-Hartley guinea pigs were fed a pelleted high cholesterol (0.5%) scorbutic diet for 5 weeks; 18 also received 0.5 mg L-ascorbic acid/day, p.o. (chronic hypovitaminosis C, group A) while 18 others received 5.0 mg L-ascorbic acid/day, p.o. (controls, group B). In group A, 14/18 animals survived at 5 weeks, had gained an average of 2.89 g, and all had gallstones, whereas in group B, 17/18 animals survived at 5 weeks, had gained an average of 25.67 g, and none had gallstones. The gallstones were found in the gallbladder and occasionally in the lumen of both the cystic and common bile ducts; the dried pooled gallstones weighed 18.96 mg, and 52.8% of this weight was cholesterol. The gallbladder bile of group A guinea pigs contained 8.99 ± 0.81 mM bile acids (BA) and 2.11 ± 0.12 mM cholesterol (C), values which were significantly different ($p<0.01$) from those of group B (14.54 ± 0.97 and 1.22 ± 0.17 mM for BA and C, resp.); however, the phospholipid (P) content was not significantly different between the two groups. Both the BA:C and P:C ratios in group A animals (4.4 and 3.7, resp.) were significantly different ($p<0.01$) from these ratios in group B animals (16.7 and 9.3, resp.), reflecting the higher C and lower BA content of group A bile. C is held in micellar solution in bile in combination with P and BA, and it has been postulated that the BA:C and P:C ratios determine the solubility of C rather than do absolute values. Thus, a lowering of these ratios favors the precipitation of C and provides a satisfactory explanation for gallstone formation in hypovitaminotic C guinea pigs.

6698 THE EFFECT OF ADRENALECTOMY UPON THE ABSORPTION, DISTRIBUTION AND METABOLISM OF ETHANOL IN THE RAT.

(Eng.) Powis, G.; Cummings, J.; Morgan, E. (Dept. Pharmacology, Glasgow Univ., Glasgow G12 8QQ, Scotland). *Life Sci.* 21(7):1033-1036; 1977.

To determine whether an altered absorption, distribution, or metabolism might enhance the toxicity of ethanol in adrenalectomized animals, male albino Wistar rats were adrenalectomized, ethanol was administered (1.0 g/kg, i.v. or 0.8 g/kg, i.p.), and blood samples were drawn at regular intervals for ethanol determinations, which were compared with control values. There was no significant difference between the peak blood ethanol levels in controls (74.5 ± 5.0 mg/100 ml) and in short-term (2-4 days before ethanol treatment) adrenalectomized rats (82.2 ± 6.3 mg/100 ml); the peaks occurred at 30 min. The peak blood ethanol level in long-term (8-14 days before ethanol treatment) adrenalectomized rats occurred at 15 min and was significantly higher than the control value (118.4 ± 1.7 mg/100 ml, $p<0.01$). The rate of ethanol metabolism did not differ significantly among the three groups. However, when the volume of distribution of ethanol and of antipyrine (10 mg and 5 μCi/kg, i.v.) were determined to measure total body water, there was a 20% reduction in total body water ($p<0.05$) in the long-term adrenalectomized rats compared with the controls. An increased rate of ethanol absorption and the decrease in total body water produced the increase in peak blood ethanol levels in long-term adrenalectomized animals. These two factors must be considered in addition to altered renal function, changes in cellular permeability, and decreased hepatic metabolism as variables that could alter the action of drugs in cases of adrenal hypofunction.

6699 THE EFFECT OF CERTAIN ANAESTHETIC AGENTS ON THE ACTIVITY OF RAT HEPATIC δ-AMINOLAEVULINATE SYNTHETASE.

(Eng.) Moore, M. R.; Parikh, R. K. (Univ. Glasgow Dept. Materia Medica and Therapeutics, Glasgow, Scotland). *Biochem. Soc. Trans.* 5(5):1473-1475; 1977.

The effect on rat hepatic δ-aminolevulinate synthetase (ALS) activity of various anesthetic agents was examined to determine if any of these drugs is porphyrinogenic. Rats were sacrificed after anesthetic treatment and their livers prepared for assay for ALS. The control level of ALS was 37.2 ± 15.2 nmol/hr/g of protein. Of 17 anesthetics tested, 7 caused increased ALS activity: thiopentone, 79.1 ± 20.0; methohexitone, 89.6 ± 28.3; althesin, 96.8 ± 22.6; chlordiazepoxide, 50.6 ± 12.4; pentazocine, 53.9 ± 13.0; ethrane, 53.8 ± 10.6; and methyoxyflurane, 53.3 ± 16.7 nmol/hr/g of protein. Barbiturate-based anesthetic drugs (thiopentone and methohexitone) could be expected to produce this effect based on previous evidence of porphyrinogenicity by barbiturates; a similar argument concerning steroids could explain the action of althesin. Pentazocine contains an allyl grouping, which is known to be porphyrinogenic in other compounds. The actions of chlordiazepoxide, methoxyfurane, and ethrane are difficult to explain; the former is known to inhibit electron transport and the second is known to cause hepatic artery spasm, which may play some part. Suc porphyrinogenic drugs should be avoided in the anesthetic management of porphyric individuals.

6700 INVESTIGATION ON THE MORPHOKINETIC REACTIONS OF THE RAT LIVER TO ETHER ANAESTHESI OF DIFFERENT DURATIONS.

(Ger.) Hildebrand, R.; Rucker, P. (Anatomisches Institut, Vesaliusweg 2-4, D-4400 Munster, W. Germany). *Anaesthesia* 25(10): 481-485; 1976.

The volumes of cell nuclei were measured in the central, intermediate, and peripheral zones of the liver lobules of adult male albino rats (specific pathogen-free Wistar TNO W 70 strain) during diethylether anesthesia lasting 15, 40, or 80 min. The mean nuclear volume in the central zone of the liver lobule was 128.26 μm^3 in the untreated controls, 128.61 μm^3 after 15-min anesthesia, 123.65 μm^3 after 40-min anesthesia ($p<0.001$), and 139.14 μm^3 after 80-min anesthesia ($p<0.001$). In the intermediate zone, the mean nuclear volume was 163. μm^3 in the controls, 156.94 μm^3 after 15-min anesthesia, 163.56 after 40-min anesthesia, and 172.61 μm^3 after 80-min anesthesia ($p<0.001$). In the peripheral zone of the hepatic lobule the mean nuclear volume was 129.73 μm^3 in the controls, and 114.09-121.36 μm^3 in the anesthetized groups ($p<0.001$). The results are interpreted by the typical distribution of cell organelles, enzymatic pathways, and metabolites in the different zones of the hepatic lobule. The intensity of the reaction and the onset of the diminution of the nuclear volume, indicating a functional depression and probably accentuated by a circulation-dependent low O_2 tension in the tissue, is interpreted in connection with different local concentrations of ether. An improvement of the blood flow by a locally increased metabolite level and an increased arterial influx presumably facilitate the recovery and favor a concentration-dependent induction of microsomal enzymes especially in the central zone of the hepatic lobule.

6701 STIMULATION OF LIVER REGENERATION BY CLOFIBRATE. (Eng.) Seifter, E.; Rettura, G.; Padawar, J.; Tolia, K.; Levenson, S. M. (Albert Einstein Coll. Medicine, Bronx, NY). *Surg. Forum* 28:395-397; 1977.

To examine the action of clofibrate, a compound known to produce nonfatty hepatomegaly, 32 adult male Sprague-Dawley rats were fed either a standard laboratory rat chow (groups 1A and 1B) or the same chow containing 2 g/kg clofibrate (groups 2A and 2B) for 3 days. Groups 1B and 2B were then subjected to 30% hepatectomy and groups 1A and 2A served as unoperated controls. Clofibrate increased liver size in controls (14.8 versus 12.6 g, $p<0.001$) and in the partially hepatectomized rats (13.4 versus 9.5 g, $p<0.001$). There were no changes in the proportions of liver protein, fat, or water due to clofibrate in either experimental or control rats. In a second experiment, 40 male Long-Evans rats were divided into 6 groups (2 with no surgery, 2 with sham operation, 2 with 30% hepatectomy with 1 group from each pair also receiving clofibrate). Clofibrate induced hepatomegaly in all three groups (liver weight 16.1 ± 1.0 versus 12.1 ± 0.6 g, 16.3 ± 0.6 versus 12.1 ± 0.4 g, and 14.0 ± 0.6 versus 10.7 ± 0.7 g, $p<0.003$, $p<0.001$, and $p<0.005$ for no surgery, sham operation, and partial hepatectomy, resp.). Clofibrate also increased the amounts of liver DNA, RNA, and protein and modestly increased the proportion of liver fat but did not increase the proportion of liver water in all three groups. It is hypothesized that clofibrate-induced hepatomegaly in normal animals occurs by an increase in cytoplasmic protein content, cell size, and either the number of nuclei/cell or the DNA content of the nuclei, whereas in partially hepatectomized rats, clofibrate causes a disproportionate increase in liver DNA, suggesting DNA synthesis or cell division.

6702 IN VIVO EFFECTS OF Escherichia coli ENDOTOXIN ON SULFOBROMOPHTHALEIN CLEARANCE IN THE GUINEA-PIG. (Eng.) Utili, R.; Abernathy, C. O.; Aron, S. A.; Zimmerman, H. J. (Veterans Admin. Hosp., Washington, DC 20422). *Experientia* 33(12): 1631-1632; 1977.

Since the incidence of cholestatic jaundice associated with gram-negative bacterial infections appears to be more prevalent in newborns than in adult humans, the effects of *Escherichia coli* endotoxin on the excretory processes of Hartley guinea pigs of different ages were studied. Lipopolysaccharide (LPS) from *E. coli* (35 µg/100 g) was administered i.p. to 1-, 3-, and 7-day-old animals, and 2 hr later, BSP (1.2 mg/100 g) was given by intracardiac injection. In saline-treated controls, BSP storage in the liver decreased between days 1 and 7, indicating maturation of hepatic conjugative processes. At 1 day, hepatic BSP accounted for about 21% of the applied dose, but at 3 and 7 days, only about 4%. In the experimental animals, LPS increased the percent BSP retention in the 1- and 3-day groups, but not in the 7-day group. At all ages, LPS caused an increased hepatic BSP storage, whether expressed in µg/g liver (136 ± 20, 95 ± 15, and 35 ± 6 µg/g liver in 1-, 3-, and 7-day-old animals, resp., versus 67 ± 20, 13 ± 3, and 14 ± 5 µg/g liver, resp., in controls) or as percentage of the applied dose (52 ± 5, 31 ± 5, and 11 ± 6%, resp., versus 21 ± 6, 4 ± 1, and 4 ± 5%, resp.). These results suggest that the primary effects of *E. coli* endotoxin on the hepatic clearance of BSP are at the excretory level.

6703 INFLUENCE OF SOME HEPATOTOXIC AGENTS ON HEPATIC GLUTATHIONE LEVELS IN MICE. (Eng.) Siegers, C. P.; Schutt, A.; Strubelt, O. (Medizinische Hochschule Lubeck, Lubeck, W. Germany). *Proc. Eur. Soc. Toxicol.* 18:160-162; 1977.

To determine whether hepatic glutathione (GSH) depletion is a reliable parameter of hepatotoxicity, hepatic levels of GSH and of oxidized GSH (GSSG) were determined in male NMRI mice 1 hr after p.o. treatment with CCl_4 (0.1 ml/kg), allyl alcohol (AA, 0.5 ml/kg), thioacetamide (TA, 50 mg/kg), dimethylnitrosamine (DMN, 150 mg/kg), bromobenzene (BB, 0.25 ml/kg), phenacetin (P, 1,000 mg/kg), and paracetamol (PA, 50 mg/kg), or after i.p. injection with diethylmaleate (DEM, 0.6 ml/kg). These levels were compared with those in controls (10 ml/kg saline, p.o.). The tested agents caused a depletion of hepatic GSH that, expressed as percentage decrease from control, amounted to 33.5% for CCl_4, 44.4% for AA, 26.8% for TA, 20.8% for DMN, 75.0% for BB, 60.1% for P, 90.1% for PA, and 81.6% for DEM. However, P and DEM did not induce hepatic lesions. The decreases in GSH levels were accompanied by corresponding decreases in GSSG levels. Pretreatment with DEM (0.6 ml/kg, i.p.) 1 hr prior to treatment with the hepatotoxins enhanced the toxicity of CCl_4, AA, BB, and PA as seen by the levels of serum enzymes (significant [$p=0.5$] increases in 2 of 3 measured enzymes in each case) and by enhanced mortality (2/12, 3/12, and 3/12 for AA, BB, and PA with DEM, resp., compared with 0/12 for each agent alone). DEM-induced GSH depletion is a useful experimental model to study the sensitivity of a GSH-depleted liver to hepatotoxic agents. Depletion of hepatic GSH is not a reliable parameter of hepatotoxicity.

6704 RAT HEPATOCYTES AND SINUSOIDAL CELLS. SIMULTANEOUS ISOLATION AND ACTIVITY OF UREA CYCLE ENZYMES. (Eng.) Kreusch, J.; Hofmann, F.; Maier, K. P.; Decker, K. (Biochemisches Institut an der Medizinischen Fakultat der Universitat Freiburg, Hermann-Herder-Str. 7, D-7800 Freiburg, W. Germany). *Hoppe Seylers Z. Physiol. Chem.* 358(11): 1513-1516; 1978.

A method for the simultaneous isolation of rat hepatocytes and sinusoidal cells from the same liver was developed and used to study the hepatic metabolism of urea. Hepatocytes were obtained from the slow-speed sediment following collagenase treatment of livers from female Wistar rats. Sinusoidal cells were obtained from the hepatocyte supernatant by incubation with pronase. When the initial centrifugation was carried out at 37 x *g* instead of 50 or 100 x *g*, the proportion of sinusoidal cells in the supernatant was high enough for efficient isolation (the ratio of sinusoidal cells to hepatocytes was 15.5). The lesser proportion of hepatocytes in the supernatant permits shorter incubations (45 min) with lower concentrations (0.15%) of pronase than were previously needed, and this has the advantage of destroying fewer sinusoidal cells. The yield of sinusoidal cells was 13.7 ± 0.6 mg (wet weight) with 14 ± 3 hepatocytes/10^4 sinusoidal cells. The leakage of lactate dehydrogenase and glutamate dehydrogenase activities from sinusoidal cells into the medium after 20 min of pronase incubation was 37% and 32%, resp., of the activity in the medium and sediment. Measurements of the activities of urea cycle enzymes in these cells revealed that the activities of carbamoyl-phosphate synthetase, ornithine carbamoyltransferase, arginosuccinate synthetase, arginosuccinate lyase, and arginase were similar in both kinds of cells but that the activity of ornithine-oxo-acid transaminase was markedly higher in sinusoidal cells than in hepatocytes (11.8 ± 4.2 versus 2.7 ± 2.5 nmol/min/mg protein). The decreased yield of sinusoidal cells by this method compared with the previous method is balanced by the ability to isolate both hepatocytes and sinusoidal cells simultaneously from the same liver. The study also confirms a previous report that the synthesis of urea occurs in sinusoidal cells as well as in hepatocytes.

6705 EFFECT OF THIOACETAMIDE ON LIVER MITOCHONDRIAL ENZYMES--CARBAMYL-P-SYNTHETASE AND ORNITHINE TRANSCARBAMYLASE. (Eng.) Feijoo, B.; Cascales, C.; Cascales, M.; Santos-Ruiz, A. (Facultad de Farmacia, Madrid, Spain). *Proc. Eur. Soc. Toxicol.* 18:262-264; 1977.

To better understand the pathogenesis of liver diseases, changes in the enzymes of the urea cycle in rat liver were studied following thioacetamide administration (TAM, 50 mg/kg/day, i.p., for 24-30 days) in male Wistar rats and compared with control values. The levels of ammonia and urea (expressed as μmol of ammonia/g of liver) in the livers of TAM-treated rats (710 ± 146 and 7,188 ± 155, resp.) were significantly different from the levels in controls (285 ± 32 and 8,995 ± 115, resp., $p<0.01$ for both). TAM produced a significant decrease ($p<0.001$) in the activities of carbamyl-P-synthetase, ornithine transcarbamylase, and arginase compared with control values (0.65 ± 0.2 versus 2.55 ± 0.15, 67.2 ± 4.8 versus 161.1 ± 19.5, and 2,088 ± 229 versus 3,367 ± 269 μmol/mg protein/hr, resp.) and a significant increase in glutamate dehydrogenase activity compared with the control value (23.2 ± 2.4 versus 13.95 ± 2.24 μmol/mg protein/hr, $p<0.01$). These results indicate a significant disturbance of the urea cycle; the inhibition of the urea cycle leads to an increase in the level of ammonia, which inhibits 2-oxoglutarate formation and, hence, glutamate formation. Thus, both mechanisms by which a cell protects itself from the toxic effects of ammonia accumulation (the urea cycle and glutamine formation) are compromised.

6706 THE EFFECTS OF INTRAVENOUS SODIUM OCTANOATE ON THE RHESUS MONKEY. (Eng.) Rabinowitz, J. L.; Staeffen, J.; Aumonier, P.; Blanquet, P.; Vincent, J. D.; Daviaud, R.; *et al.* (Philadelphia Veterans Admin. Hosp., Philadelphia, PA). *Am. J. Gastroenterol.* 69(2):187-190; 1978.

Experience with sodium octanoate-induced coma in primates is presented to assess the role of octanoate in hepatic encephalopathy. Five adult female Rhesus monkeys received sodium octanoate (5 mM/kg using a 0.625 M solution in isoosmotic NaCl adjusted to pH 7.35 with HCl, i.v., over a 10-min period). Two minutes after the beginning of infusion, muscular hypotony developed in all animals followed by the appearance of sleep characterized by slow, high-amplitude encephalographic waves. Slow (12/min) myoclonic movements then developed involving the entire body but with predominant activity in the extremities. This phenomenon was followed by a period of approximately 10 min in which there was almost complete muscle atony as in paradoxical sleep without eye movement; the electroencephalogram (EEG) registered 1.5 cycle/sec rhythmical activity. This phase was followed by a period of nonrhythmical EEG paroxyms occurring with bi- or triphasic wave patterns. Neck muscle activity slowly reappeared, followed by rapid eye movement and delta waves. The polygraph returned to normal 40 min after the beginning of infusion, at which time the EEG became desynchronized. In 190 octanoate determinations performed in 24 control subjects and 79 patients with cirrhosis of whom 50 were in some stage of hepatic encephalopathy, arterial and venous concentrations of octanoate were significantly higher in cirrhotic patients than in controls ($p<0.01$) and in cirrhotic patients in coma than in cirrhotic patients not in coma ($p<0.05$). Serum octanoate levels in cirrhotic patients were frequently above 10 μEq/l with a maximum level of 18 μEq/l (normal value, <5 μEq/l with a mean value cf 1.5 μEq/l). In comatose patients, there appeared to be a correlation between blood octanoate and ammonia levels.

It remains uncertain as to whether elevated serum octanoate level is a causative factor of hepatic encephalopathy or an incidental finding resulting from serious hepatic disease.

6707 THE RELATIONSHIP BETWEEN MEMBRANE POTENTIAL AND ATP CONTENT IN RAT LIVER DURING ISCHEMIA.

(Eng.) Shiba, Y.; Muneoka, Y.; Kanno, Y. (Sch. Dentistry, Hiroshima Univ., 2-3 Kasumi 1 Chome, Hiroshima 734, Japan). *Experientia* 15(1): 57-58; 1978.

To determine whether the decrease in the membrane potential of the liver caused by ischemia is explained by the ATP-depleting effect of ischemia, the effects of ischemia on the membrane potential and ATP content in the livers of ethionine-treated and untreated female Donryu rats were investigated. Ischemia was induced by occluding both the portal vein and common hepatic artery. DL-ethionine (75 mg/100 g) was injected i.p. 5.5 hr before ischemia was induced. The membrane potential and ATP content in the livers of untreated rats were -52.4 ± 3.6 mV and 2.43 ± 0.25 μmol/g wet liver, resp. These values decreased to -43.8 ± 4.4 mV and 0.44 ± 0.13 μmol/g wet liver, resp., in the ethionine-treated rats. Both ischemia and ethionine decreased the membrane potential and ATP content. In ethionine-treated liver, ischemia brought about a further significant decrease in membrane potential ($p<0.01$) without a significant decrease in ATP content ($0.1<p<0.2$). The results suggest that the decrease in the membrane potential by ischemia cannot be fully explained by its ATP-depleting effect.

6708 THE ACUTE PHASE RESPONSE TO INJURY AND ITS RELATIONSHIP TO CHANGES IN ENDOPLASMIC RETICULUM OF RAT LIVER.

(Eng.) Turchen, B.; Jamieson, J. C.; Huebner, E.; Van Caeseele, L. (Dept. Chemistry, Univ. Manitoba, Winnipeg, Manitoba R3T 2N2, Canada). *Can. J. Zool.* 55(9):1567-1571; 1977.

The ultrastructural changes that accompanied the acute phase response of serum proteins to experimental liver injury were investigated in male rats. The rats received an s.c. injection of either turpentine (0.5 ml/100 g) or 0.15 M NaCl and were killed 8, 12, 24, or 48 hr later. The induction of the acute phase response to injury was accompanied by dilation and loss of the regular structural features of the endoplasmic reticulum membranes. There were numerous circular or oval vesicles of rough and smooth endoplasmic reticulum. In most livers, there appeared to be increases in the amounts of smooth endoplasmic reticulum and Golgi complex relative to rough endoplasmic reticulum. These changes were present in all experimental animals, but were most noticeable in those with injury for 12-24 hr. The mean levels of sialyltransferase, galactosyltransferase, protein, RNA, phospholipid, protein-bound sialic acid, protein-bound galactose, albumin, and α_1-acid glycoprotein in the experimental animals at 24 hr (1,170 pmol/hr/mg protein [sialic acid transferred], 780 pmol/hr/mg protein [galactose transferred], 31.6 mg/g wet weight liver, 5.2 mg/g wet weight liver, 9.7 mg/g wet weight liver, 34.7 μg/g wet weight liver, 23.8 μg/g wet weight liver, 308.0 μg/g wet weight liver, and 280.0 μg/g wet weight liver, resp.) were increased in comparison with the levels in controls (650 pmol/hr/mg protein, 480 pmol/hr/mg protein, 27.8 mg/g, 4.8 mg/g, 7.2 mg/g, 25.5 μg/g, 18.0 μg/g, 389.0 μg/g, and 78 μg/g, resp.). It is suggested that the ultrastructural and biochemical changes in the liver result in part from an increased demand for liver synthesized glycoproteins.

6709 LONG-TERM EFFECT OF ARTERIALIZATION OF THE PORTAL VEIN ON THE SINUSOIDAL PRESSURE IN DOGS WITH PORTACAVAL SHUNT.

(Eng.) Arif, S.; Butt, K.; Dennis, C.; Lam, A.; Minkowitz, S.; Babich, A.; *et al.* (Downstate Medical Center, State Univ. New York, Brooklyn, NY). *Surg. Forum* 28:406-407; 1977.

Arterial flow into the portal vein after arterialization of the intrahepatic portal vein following portacaval shunt was monitored, and excessive perfusion was prevented by the choice of a small arteriovenous fistula, to determine the sinusoidal pressure in a chronic dog preparation. The hepatic vein wedge pressure (sinusoidal pressure) was determined manometrically preoperatively and at 2 weeks, 6 months, and 12 months postoperatively, and thereafter at 12- to 20-month intervals. In control dogs (portacaval shunt only), the mean preoperative sinusoidal pressure was 18.3 cm of saline; a slight decrease was observed after 2 weeks (16.4 cm), and in one dog that survived 6 months, the pressure was 12 cm. In 17 experimental dogs, the mean preoperative sinusoidal pressure was 17.4 cm of saline, and no abnormal elevations were seen during 56 months of follow-up. No significant changes in portal flow were observed up to 48 months, except in one animal in which a 2.63-fold increase in flow was measured after 24 months. The sinusoidal pressure did not change in this experimental preparation because the volume of blood entering the sinusoidal bed was similar to normal portal vein flow. Because the hemodynamics of the sinusoidal bed remained essentially unchanged, there was no damage to hepatic parenchyma.

6710 ENHANCEMENT OF THE ANTI-ANABOLIC RESPONSE TO ADENOSINE 3':5'-CYCLIC MONOPHOSPHATE DURING DEVELOPMENT: THE INHIBITION OF HEPATIC PROTEIN SYNTHESIS.

(Eng.) Klaipongpan, A.; Bloxham, D. P.; Akhtar, M. (Dept. Physiology, Univ. Southampton, Southampton SO9 3TU, England). *Biochem. J.* 168(2):271-275; 1977.

Intestine

34 DISTRIBUTION OF INTRINSIC NERVE CELL BODIES AND AXONS WHICH TAKE UP AROMATIC AMINES D THEIR PRECURSORS IN THE SMALL INTESTINE OF THE INEA-PIG. (Eng.) Furness, J. B.; Costa, M. (Sch. dicine, Flinders Univ., Bedford Park, South Aus- alia, 5042, Australia). *Cell Tissue Res.* 188(3): 7-543; 1978.

e sites of uptake, decarboxylation, and retention L-dopa and the uptake and retention of dopamine d 6-hydroxytryptamine in the guinea pig small testine were localized histochemically with a uorescence technique for arylethylamines. In eal segments from untreated guinea pigs, only radrenergic axons were fluorescent; these axons re eliminated by surgical denervation (crushing rves running to the intestine through the mes- tery) or by chemical denervation with 6-hydroxy- pamine (300 mg/kg and 200 mg/kg, s.c., 1 week art). In denervated segments of ileum, cell bodies d processes of intrinsic neurons became fluorescent ter the injection of l-dopa (175 mg/kg), dopamine 0-200 mg/kg), or 6-hydroxytryptamine (20-100 mg/) and the inhibition of monoamine oxidase, as did lls of Brunner's glands and Paneth cells. About % of the nerve cell bodies in the submucous plexus and 0.4% of those in the myenteric plexus became fluorescent. Varicose intrinsic axons that took up amines were found among the nerve cell bodies of the myenteric and submucous plexuses. They also ramified in the principal connections of the plexuses, in the tertiary strands of the myenteric plexus, in the deep muscular plexus, and contributed sparse supplies of axons to arterioles in the submucosa and to the lamina propria of the mucosa. The axons were resistant to the degenerative actions of 6-hydroxydopamine. It is suggested that the intrinsic amine handling axons are more likely to utilize an indolamine related to 5-hydroxytryptamine than they are to utilize a catecholamine as a neurotransmitter.

6735 ACID RELEASES MOTILIN FROM HUMAN DUODENUM IN VITRO. (Eng.) Strunz, U.; Mitznegg, P.; Domschke, W.; Subramanian, N.; Domschke, S.; Wunsch, E. (Dept. Medicine, Univ. Erlangen-Nurnberg, Erlangen, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 24(6):456-457; 1977.

The effects of hydrochloric acid and sodium hydroxide on human duodenal mucosa were studied using an *in vitro* perfusion technique to investigate the stimuli for motilin release. Motilin was measured by a sensitive and specific radioimmunoassay. The pH of the perfusate was adjusted either to pH 2 by addition of 1 N HCl or to pH 12 by addition of 1 N NaOH, and samples of the effluent were taken at timed intervals. The tissue was obtained from patients undergoing gastrectomy for chronic ulcer disease or gastric cancer. Under basal conditions (pH 7.5), 2.2 ± 0.3 fmol motilin/min/100 mg tissue were released into the medium. Alkalinization completely abolished this release. Acidification caused a peak release of 31.7 ± 3.1 fmol motilin/min/100 mg tissue after 1 min. Motilin levels remained markedly elevated for 40 min, whereas the pH returned to 7.5 within 2 min after addition of the acid. It is concluded that motilin secretion can be stimulated *in vitro* and that this perfusion system may be useful in studying the mechanism of gastrointestinal hormone release.

6736 INTESTINAL DISACCHARIDASES IN NEWBORN AND MOTHER RATS: EFFECT OF DIETARY PROTEIN DEFICIENCY DURING PREGNANCY.

(Eng.) Younoszai, M. K.; Swanson, J. D., Jr.; Ranshaw, J. (Coll. Medicine, Univ. Iowa, Iowa City, IA 52242). *Am. J. Clin. Nutr.* 31(6):931-937; 1978.

Small intestinal growth and disaccharidase activity were studied in mother rats fed a protein-deficient diet during pregnancy and in the pups. Pups were delivered at term, by cesarean section, from control (CP) and test (TP) rats. The diets fed during pregnancy contained 26% casein (CP rats) or 6% casein (TP rats). At birth, body weight and small intestinal length and weight were significantly lower in pups of TP than in those of CP rats ($p<0.01$). Specific activity of lactase in the small intestine was similar in the two groups of pups (mean 106 versus 116 μmol lactose hydrolyzed/min/g protein). However, total activity of lactase in the entire small intestine was significantly lower in the pups of TP than in those of CP rats ($p<0.01$). In the mothers, the weight of the small intestine in TP rats was almost half that in the CP rats (3.7 versus 7.6 g). In the mucosal scrapings of distal third of the small intestine, specific activities of the disaccharidases were significantly greater in TP than in CP rats (lactase, 15.0 versus 6.2; sucrase, 39 versus 21; maltase, 250 versus 152 μmol substrate hydrolyzed/min/g protein of mucosal homogenate). In the proximal third of the small intestine, only maltase activity was significantly ($p<0.05$) different (lactase, 12.0 versus 10.8; sucrase, 76 versus 61; maltase, 350 versus 258 μmol/min/g). Total activities of the disaccharidases in the small intestine were significantly lower ($p<0.05$) in the TP than CP rats (lactase, 4.0 versus 6.4; sucrase, 15 versus 28; maltase, 74 versus 125 μmol hydrolyzed/min, by mucosal scrapings of the entire intestine). This study did not indicate that in the small intestine specific activity of lactase was lower in the growth retarded than in the controls. However, total activity of lactase in the entire small gut was significantly lower because of the small size of the intestine in the former group.

6737 LACTASE ENZYMES IN THE INTESTINAL BRUSH BORDER MEMBRANE OF THE SUCKLING RAT: A SECOND ENZYME RESTRICTED TO ILEUM.

(Eng.) Green, J. R.; Hauri, H. P. (Univ. Children's Hosp., 3010 Bern, Switzerland). *FEBS Lett.* 84(2):233-235; 1977.

A specific assay for brush border membrane lactase was used to study the small intestine of 1- to 28-day-old rats. This study confirmed the developmenta differences in lactase activity reported in other studies. Lactase activity in the distal small intestine increased from an initial low level to reach a peak between days 8 and 16, after which it decreased and was totally absent by day 28; activit in the proximal intestine showed little change unti day 16 when it began to fall to approach adult values by day 28. The possibility that the proxima and distal lactases are not identical molecules was investigated by gel electrophoresis. A comparison of the protein and enzyme patterns showed that the lactase activity of suckling rats comigrates with a major protein band of relative front (R_F) 0.277 for the proximal enzyme and R_F 0.242 for the distal one To locate more precisely the change-over point between the proximal and distal lactases, the small intestines from rats aged 12, 14, 19, and 23 days were divided into eight sections of equal length and the brush border membrane proteins analyzed. From the R_F values, it was possible to classify the enzyme present in sections 1-6 as the proximal type and that in sections 7 and 8 as the distal type. In no section was the simultaneous presence of the two forms of the enzyme observed, and there was no evidence for a gradual change in mobility of any of the bands that would be expected if the observed differences were due to intraluminal proteolysis of a proximal protein to produce an electrophoretically faster distal form. The results demonstrate that there is a second type of lactase molecule restricted to the distal small intestine of the suckling rat.

6738 EFFECT OF ALLOXAN-INDUCED DIABETES ON INTESTINAL PEPTIDASES IN THE RAT.

(Eng.) Arvanitakis, C.; Folscroft, J.; Stitt, G. (Kansas Univ. Sch. Medicine, Kansas City, KS 66103). *Endocrinology* 102(4):1118-1121; 1978.

Inasmuch as amino acid transport is increased in diabetes and intestinal peptidases are important enzymes in the digestion and absorption of peptide and amino acids, the effect of experimental diabetes on representative membrane-bound and cytoplasmic peptidases was examined in the rat small intestine. Male Holtzman rats received either alloxan monohydrate (40 mg/kg) or normal saline (control) i.v., and 24-hr urine was collected and tested for glucose. Persistent glucosuria, hyperglycemia (blood glucose >250 mg/dl), and weight loss were the criteria for diabetes. There was no significant difference in daily food intake between the groups. On day 7 after treatment, the rats were sacrificed, and proximal and distal halves of the entire small intestinal mucosa were processed to obtain brush border and cytosol-fraction enzymes. Alloxan diabetes significantly increased the wet weight of the mucosal scrapings and total mucosal protein in both the proximal (from 2.25 ± 0.2 to 3.15 ± 0.4 g and from 0.214 ± 0.02 to 0.359 ± 0.02 g, resp., $p<0.01$) and distal segments (from 1.59 ± 0.2 to 2.26 ± 0.3 g and from 0.189 ± 0.01 to 0.268 ± 0.02 g, resp., $p<0.025$ and $p<0.05$, resp.). When the activities of leucyl-naphthylamidase (LNA), leucyl-glycine hydrolase (LGH), and prolyl-glycine hydrolase were assayed, there were no significant differences in cytosol fraction activities between control and diabetic rats, but the total and specific activities of LNA and LGH were significantly increased in both the proximal ($p<0.02$ and $p<0.05$, resp., for LNA; $p<0.05$ and $p<0.05$, resp., for LGH) and distal segments ($p<0.02$ and $p<0.02$, resp., for LNA; $p<0.05$ and $p<0.05$, resp., for LGH). The results demonstrate that peptidase activities of the intestinal brush border but not of the cytoplasm are increased in experimental diabetes throughout the small intestine in the rat and that the increase is not due to dietary factors.

6739 UREASE AS A CONTRIBUTING FACTOR IN ULCERATIVE LESIONS OF THE COLON. (Eng.)

LeVeen, E. G.; Falk, G.; Ip, M.; Mazzapica, N.; LeVeen, H. H. (State Univ. New York, 450 Clarkson Ave., Brooklyn, NY 11203). *Am. J. Surg.* 135(1):53-56; 1978.

Studies were carried out in dogs to determine whether ammonia is involved in the pathogenesis of colonic ulcerations in uremia. Bilateral nephrectomies or ureteral ligations were performed in 16 dogs, and 8 were immunized with enzymatically inactive urease and tested for the presence of antibodies on an Ouchterlony plate. The serum was also tested chemically to see whether it inhibited the enzymatic conversions of urea to ammonia. Massive hemorrhagic ulcerative colitis was found in six of the eight control dogs that underwent one of the operations, and all died before the sixth postoperative day. All immunized dogs were alive and well 5 days after nephrectomy, and the gastrointestinal tracts were grossly and histologically normal. The mean blood urea nitrogen level for the immunized group was 410 mg/100 ml at the time of sacrifice and 285 mg/100 ml in the nonimmunized animals just prior to death. Portal vein ammonia levels increased in the controls but did not increase significantly in the immunized animals. These results prove that the colonic ulcerations seen in uremia are the result of excessive colonic ammonia production.

6740 DIGESTION OF CERTAIN FRACTIONS OF DIETARY FIBER IN HUMANS. (Eng.)

Holloway, W. D.; Tasman-Jones, C.; Lee, S. P. (Auckland Hosp., Auckland, New Zealand). *Am. J. Clin. Nutr.* 31(6):927-930; 1978.

Studies were carried out to determine if there is cellulose, hemicellulose, or lignin digestion in the human small or large bowel. Six healthy subjects with an ileostomy and 10 normal subjects were studied. Both were put on a fixed diet of known cellulose, hemicellulose, and lignin content. From the feces excreted, the fiber components were measured by the acid and neutral detergent method. From the small bowel, 84.5% of the ingested cellulose was excreted from the ileostomy subjects. From the normal subjects, 22.4% of the ingested cellulose was excreted, indicating that approximately 80% of the cellulose was digested in the large bowel of normal subjects. Of the water insoluble ingested hemicellulose, 27.5% was excreted from the small bowel of the ileostomized patients and 4.0% was excreted by the large bowel of the normal subjects. There is thus approximately 96% digestion of hemicellulose in normal subjects. Lignin was not digested by the small or large bowel. These studies indicate that hemicellulose and cellulose are both digested, mainly in the small intestine in the former case and in the large intestine in the latter case. Hemicelluloses may contribute significantly to the caloric value of foods. Since cellulases are not present in human digestive juices, fiber digestion is probably by intestinal bacteria.

6741 SYNTHESIS OF PLASMALEMMAL GLYCOPROTEINS IN INTESTINAL EPITHELIAL CELLS: SEPARATION OF GOLGI MEMBRANES FROM VILLUS AND CRYPT CELL SURFACE MEMBRANES; GLYCOSYLTRANSFERASE ACTIVITY OF SURFACE MEMBRANE. (Eng.)

Weiser, M. M.; Neumeier, M. M.; Quaroni, A.; Kirsch, K. (Harvard Medical Sch., Boston, MA 02114). *J. Cell Biol.* 77(3):722-734; 1978.

The relationship between Golgi and cell surface membranes of intestinal cells with respect to glycosyltransferase activities was studied. These membranes were isolated from intestinal crypt cells and villus cells. The villus cell membranes consisted of microvillus membrane, a Golgi-rich fraction, and two membrane fractions interpreted as representing lateral-basal membranes. The villus cell microvillus membrane was purified by previously published techniques, while the other membranes were obtained from isolated cells by differential centrifugation and density gradient velocity sedimentation. The two membrane fractions obtained from villus cells and considered to be lateral-basal membranes were enriched for Na^+,K^+-ATPase activity, but one also showed enrichment in glycosyltransferase activity. The Golgi membrane fraction was enriched for glycosyltransferase activity and had low to absent Na^+,K^+-ATPase activity. Adenylate cyclase activity was present in all membrane fractions except the microvillus membrane but copurified with Golgi rather than lateral-basal membranes. Electron microscopy showed that the Golgi fraction consisted of variably sized vesicles and cisternalike structures. The two lateral-basal membrane fractions showed only vesicles of smaller, more uniform size. After ^{125}I labeling of isolated intact cells, radioactivity was found to be associated with the lateral-basal and microvillus membrane fractions and not with the Golgi fraction. Antibody prepared against lateral-basal membrane fractions reacted with the surface membrane of isolated villus cells. The membrane fractions from isolated crypt cells demonstrated that all had high glycosyltransferase activity. The data show that glycosyltransferase activity, in addition to its Golgi location, may be a significant property of the lateral-basal portion of the intestinal villus cell plasma membrane. Data obtained with crypt cells support earlier data and show that the crypt cell surface membrane possesses glycosyltransferase activity.

6742 STUDIES ON TRANSLOCATION OF IMMUNOGLOBULINS ACROSS INTESTINAL EPITHELIUM. III. FAILURE OF CHOLERA ENTEROTOXIN TO STIMULATE SECRETION OF IgA BY RABBIT INTESTINE. (Eng.) Borthistle, B. K.; Isobe, K.; Brown, W. R. (Univ. Oregon Medical Center, 3181 S.W. Sam Jackson Park, Portland, OR 97201). *Am. J. Dig. Dis.* 23(2):134-136; 1978.

To test the hypothesis that secretion of IgA into intestinal fluids is modulated by increases in epithelial cell cyclic AMP (cAMP) levels, purified cholera enterotoxin (10 μg to 1 mg) was instilled into jejunal loops of adult New Zealand white rabbits for 10 min, after which fluid was collected from each loop at hourly intervals for 8 hr. The levels of IgA in these specimens were compared to those in specimens from saline-treated controls by radial immunodiffusion. The fluid collected from 10-μg toxin-stimulated loops was about fivefold that from control loops (10.6 ± 1.0 versus 2.0 ± 0.5 ml/8 hr). At higher toxin doses, there was no increase in fluid response. The total amount of IgA collected from the 10-μg toxin-stimulated loops and from the control loops was similar (21.2 ± 5.1 versus 19.5 ± 3.7 mg/g loop/8 hr) and did not increase at higher toxin doses; hence, the IgA concentration fell in toxin-stimulated loops due to the increase in fluid secretion. The results suggest that the transepithelial transport of IgA into the intestinal lumen is not modulated by cholera-toxin induced increases in intraepithelial cell cAMP, but it is not possible to conclude that intestinal secretion of IgA is never modulated by increases in epithelial cell cAMP.

6743 MICROPROBE MEASUREMENT OF Na, K, AND Cl CONCENTRATION PROFILES IN EPITHELIAL CELLS AND INTERCELLULAR SPACES OF RABBIT ILEUM. (Eng.) Gupta, B. L.; Hall, T. A.; Naftalin, R. J. (Biological Microprobe Lab., Cambridge, England). *Nature* 272(5648):70-73; 1978.

Electron microprobe x-ray analysis of frozen-hydrated sections was used to measure the concentration profiles of Na, K, Cl, Ca, S, and P in the mucosal tissue of rabbit ileum to elucidate how the secretion of Na$^+$ into the lateral intercellular spaces (LIS) generates a flow of water. There was a zone approximately 0.5 μm wide of peripheral cytoplasm immediately adjacent to the cell membrane and including the terminal web area where there was much less S, more P, and much less dry mass (14% of wet mass) than was found in the cell core (25% of wet mass). This zone constitutes 10-20% of cell volume, shows no significant ion gradient, but has a much higher average K concentration than in the cell core. It appears to constitute a compartment with an osmolality intermediate between the bathing medium and the LIS fluid; it may act as a channel in which ions are more mobile and are conducted by an actomyosin system. The cell core, with its high concentration of membraneous organelles, may form a relatively unstirred compartment with slower rates of diffusion. The average concentrations of Na and K in the LIS were significantly higher ($p<0.05$ and $p<0.025$, resp.) than the corresponding concentrations in the bathing solutions and in the capillary fluid. There appeared to be distinct gradients of Na, K, and Cl along the LIS and into the lamina propria, with a plateau about halfway along the channel. The concentration profile in the junctional half of the LIS showed a much steeper gradient within the wider region of the channel ($p<0.025$) than the one across the narrow junctional channel ($p<0.05$). The concentration profiles suggest a considerable osmotic flow of water across the junction into the LIS. The results establish the hypertonicity of the fluid in the LIS and the concentration gradients of Na, K, and Cl in the cells and in the LIS. It is concluded that, during the galactose-induced fluid absorption in rabbit ileum, the LIS form the primary sites of solute-water coupling.

6744 A NEW CORRELATION BETWEEN CALCIUM ABSORPTION AND INTESTINAL ALKALINE PHOSPHATASE ACTIVITY. (Fre.) Fournier, P.; Fontaine, N.; Fournier, A. (Faculte des sciences pharmaceutiques et biologiques, 92290, Chatenay-Malabry, France). *Ann. Nutr. Aliment.* 31(3):277-290; 1977.

A few male rats from an inbred Wistar strain were found to have a spontaneous highly increased ability to absorb calcium when compared to other rats from the same lot. Their calcium absorption coefficients varied from 24 to 47 compared to 13 to 22 for controls. The activity of various alkaline phosphatase preparations derived from ileal mucosa showed a corresponding increase. The activity of other enterocyte brush border enzymes, such as maltase, invertase, and leucylaminopeptidase, was comparable in both exceptional rats and controls. Similarly, there was no difference in alkaline phosphatase activity in other tissues (plasma, liver, kidney, and femur). The elevated calcium absorption and alkaline phosphatase activity were temporary, since exceptional rats bad the same skeletal weight as normals. These findings support the probability that ileal alkaline phosphatases are a factor in calcium transfer in the rat.

6745 IS THE EFFECT OF DIPHENOLIC LAXATIVES MEDIATED VIA RELEASE OF PROSTAGLANDIN E? (Eng.) Beubler, E.; Juan, H. (Institut fur experimentelle und klinische Pharmakologie, Universitats-platz 4, A-8010 Graz, Austria). *Experientia* 34(3): 386-387; 1978.

To investigate whether diphenolic laxatives exert their action via stimulation of prostaglandin (PG) biosynthesis, the diphenolic laxatives bisacodyl and phenolphthalein were compared with the osmotic laxative mannitol in female Sprague-Dawley rats. Net water flux was estimated in the *in vivo* isolated colon using the marker ^{14}C-polyethyleneglycol by measuring the change in its initial concentration over a 60-min period in response to either 4% mannitol, 1 or 10 μg/ml bisacodyl, or 100 μg/ml phenolphthalein. In separate nonisolated colon preparations, a 1-hr perfusion with Tyrode's solution (control period) was followed by a 1-hr perfusion with either 4% mannitol, 50 μg/ml bisacodyl, or 500 μg/ml phenolphthalein, and the PGE concentration in the perfusate was determined by radioimmunoassay. Control net water flux was directed from lumen to blood in the isolated colon; 1 μg/ml bisacodyl reduced this flux significantly ($p<0.05$), and 4% mannitol, 10 μg/ml bisacodyl, and 100 μg/ml phenolphthalein reversed net absorption to net secretion ($p<0.01$). Pretreatment of the rats with indomethacin (4 mg/kg/day, s.c., for 2 days), a PG synthesis inhibitor, did not affect water flux in controls or in mannitol-treated rats, but reduced the effect of 1 μg/ml and 10 μg/ml bisacodyl ($p<0.01$ and $p<0.05$, resp.) and of phenolphthalein ($p<0.01$). Net water flux was in the same direction but 1.74 times higher in the perfused colon than in the tied-off colon, necessitating larger drug doses. Bisacodyl and mannitol significantly reduced net water absorption ($p<0.01$), and phenolphthalein caused net water secretion ($p<0.01$). The amount of PGE released was 250 ± 97 pg/hr during the control period, which amount was significantly increased by bisacodyl (about threefold, $p<0.01$) and by phenolphthalein (about 4.5-fold, $p<0.01$) but was not affected by mannitol. The results suggest that diphenolic laxatives exert their action via stimulation of PGE biosynthesis in the colon.

6746 THE INFLUENCE OF STARVATION ON THE ZINC CONTENT OF PANETH CELLS OF THE RABBIT SMALL INTESTINE.

(Eng.) Singh, I. (Medical Coll., Rohtak, India). *Anat. Anz.* 142(10):502-506; 1977.

Variations in the zinc content of the Paneth cells were examined in the rabbit small intestine during feeding and starvation. No zinc was found in the uodenum of the fed controls and of the animals tarved for 24-72 hr. The zinc content increased n both controls and starved animals in the cranial-audal direction, with the highest amounts found in he terminal ileum. The mean zinc content at each f six levels of small intestine was significantly ower in the starved animals than in the controls p<0.02). These results suggest that zinc is inolved more with the synthesis of the secretory ranules of the Paneth cells, rather than in being constituent thereof.

747 SMALL INTESTINAL MORPHOLOGY AND CELL RENEWAL 72 HOURS AFTER BILE DUCT OPERATION IN RATS.

(Eng.) Ecknauer, R.; Bohmer, R. (Dept. Clinical Chemistry, Univ. Ulm, Ulm, W. Germany). *Digestion* 16(1/2):165-168; 1977.

Small intestinal morphology and epithelial cell renewal were studied in bile duct-fistulated, bile duct-ligated rats, and two different sham-operated control groups, to investigate conflicting reports of the effect of these procedures on turnover of the intestinal epithelium. Sham-operated rats were either kept in restraining cages, as were all the rats with bile duct operation, or in ordinary cages. There was no difference in crypt depth and crypt-villus ratio between the four groups of rats. The rats with bile duct ligation had the shortest villi of the four groups (349 ± 43 and 238 ± 4 μm in jejunum and ileum, resp.). Villus base length showed the same tendency as villus height in the jejunum. Villus base length was shortest in the ileum of the bile duct-fistulated rats (288 ± 21 μm). In the jejunum, villus size of all four groups was smaller than villus size reported in nonstarved rats of the same age and strain, whereas in the ileum there was no significant difference. The number of vincristine-blocked metaphases (VBM) per crypt per 2 hr (representing cell renewal) was lowest in the rats with bile duct fistulation (8.4 ± 6.0 and 5.9 ± 6.0 VBM/2 hr/crypt in jejunum and ileum, resp.) and highest in the nonrestrained sham-operated rats (18.5 ± 3.1 and 20.4 ± 3.7 VBM/2 hr/crypt, resp.). The findings are compatible with the results of a previous investigation in which a reduction in ileal DNA synthesis and in cell shedding occurred following bile duct fistulization.

6748 POSTRESECTIONAL HYPERPLASIA OF THE SMALL INTESTINE WITHOUT BILE AND PANCREATIC JUICE.

(Eng.) Shellito, P. C.; Dahl, E. P.; Terpstra, O. T.; Malt, R. A. (Shriners Burns Inst., Boston, MA 02114). *Proc. Soc. Exp. Biol. Med.* 158 (1):101-104; 1978.

To assess the role of pancreaticobiliary secretions in mediating adaptive hyperplasia of the small intestine, rats with ligation of the pancreaticobiliary duct were studied 48 hr after jejunectomy. After ligation, the rise in ileal RNA content was only 12% as compared with 44% control ($p<0.02$), and the rise in DNA content was only 13% as compared with 25% control ($p<0.01$). The results suggest that some adaptive hyperplasia can occur after pancreaticobiliary ligation, but the hyperplastic response is potentiated by pancreaticobiliary exocrine secretion.

6749 EFFECT OF EXOCRINE PANCREATIC INSUFFICIENCY ON SMALL INTESTINE IN THE MOUSE.

(Eng.) Kwong, W. K. L.; Seetharam, B.; Alpers, D. H. (Washington Univ. Sch. Medicine, 660 S. Euclid, St. Louis, MO 63110). *Gastroenterology* 74(6):1277-1282; 1978.

A genetically conditioned mouse model of exocrine pancreatic insufficiency (epi) was used to study the effect of the absence of lumenal proteases on small intestinal mucosal proteins. The small bowel was divided into eight equal segments. Enzyme activity was increased only in the first three segments in the case of maltase, sucrase, and lactase (all molecular weight >200,000). Alkaline phosphatase (molecular weight 145,000), trehalase (95,000), and peptidase (175,000) activities were unaffected in proximal segments from epi mice. Proximal brush border proteins were identified and measured quantitatively by sodium dodecyl sulfate acrylamide gel electrophoresis. Those enzymes with increased activity were associated with increased amounts of protein in epi mice. Double-label studies of protein turnover revealed a longer half-life for large brush border proteins (molecular weight >175,000) in epi mice than in normal mice. Enterokinase activity (a marker for duodenal mucosa) was nearly absent from the duodenum of epi mice. Receptors for the intrinsic factor-vitamin B_{12} complex (markers for ileal mucosa) were present in the ileum equally in normal and in epi mice. Enterokinase activity can be induced in epi mice by feeding its substrate trypsinogen, but not by trypsin or chymotrypsinogen. Epi mice thus retain the ability to synthesize enterokinase. Pancreatic proteases play an important role in the turnover of certain large mucosal proteins and in the induction of enterokinase.

6750 PROTEIN DIGESTION AND ABSORPTION IN RATS WITH PANCREATIC DUCT OCCLUSION. (Eng.) Curtis, K. J.; Gaines, H. D.; Kim, Y. S. (Veterans Admin. Hosp., 4150 Clement St., San Francisco, CA 94121). *Gastroenterology* 74(6):1271-1276; 1978.

To test the hypothesis that sufficient intraluminal digestion of dietary protein occurs to permit some absorption even in the absence of pancreatic proteolytic enzymes, the effects of pancreatic duct ligation on the digestion and absorption of a randomly ^{14}C-labeled protein meal were investigated in the rat. Although there was a significant reduction in luminal digestion and absorption of the protein meal at 3 and 4 hr in the pancreatic duct-ligated animals compared with controls ($p<0.02$ and $p<0.001$, resp.), 37% of administered protein was absorbed despite absence of luminal pancreatic proteolytic enzyme activity. To characterize further the digestive and absorptive processes that occur in the absence of luminal pancreatic proteolytic enzyme activity, whole protein meal (untreated) and protein preincubated with pepsin and HCl or HCl alone (treated) was instilled into isolated loops of rat intestine containing no demonstrable pancreatic proteolytic enzyme activity. Thirty percent absorption of the untreated protein meal occurred in 4 hr; significantly greater amounts of both treated forms of meal were absorbed ($p<0.005$ with both types of meal). It is concluded that the small bowel has the capacity to hydrolyze and absorb nutritionally significant amounts of dietary large molecular weight protein in the absence of luminal pancreatic enzyme activity. Furthermore, this process may be enhanced by prior denaturation and proteolysis in the stomach.

6751 EFFECTS OF HIGH PROTEIN DIET ON ADAPTATIONAL PROCESSES FOLLOWING SMALL INTESTINAL BY-PASS IN THE RAT. (Eng.) Macarone-Palmieri, R.; Mirkovitch, V.; Robinson, J. W. L.; Saegesser, F. (Centre Hospitalier Universitaire Vaudois, 1011 Lausanne, Switzerland). *Gastroenterol. Clin. Biol.* 2(3):279-286; 1978.

The effect of a high-protein diet on intestinal adaptation to an intestinal bypass was studied in male Wistar rats. In these animals, 70% of midintestine was excluded and drained through an end-to-side ileocecal anastomosis, while continuity was re-established between the jejunal and ileal remnants. During the 3 postoperative weeks, one group was fed with standard pellet food and the other with one of threefold greater protein content with the same daily caloric intake. The high-protein diet significantly reduced the postoperative weight gain ($F_{1,22}=4.55$). Both the jejunum and ileum in continuity in the animals on a high-protein diet retained the same rate of absorption of water, sodium, and glucose *in vivo* as that of control rats; their mucosae had normal sucrase content (1.0 ± 0.21, 0.4 ± 0.08, and 1.0 ± 0.20 IU/g in jejunum, ileum, and excluded loop, resp.), but lower phenylalanine uptake *in vitro* ($p<0.001$) and an increase in villus height in the jejunum ($p<0.005$) as compared to pellet-fed controls. The animals fed standard pellets manifested a greater jejunal water absorption, a higher mucosal sucrase content, but a less pronounced increase in villus height compared with the high-protein diet group. In the excluded intestines, which remained without intraluminal nutrition, there was no functional or morphological atrophy. The results suggest that the high-protein diet, as compared with the standard diet, was more effective in inducing an increase in the absorptive surface of the intestine in continuity during the adaptive process. Conversely, the high-protein diet resulted in an apparently greater reduction in intestinal absorption *in vivo*.

GENERAL

59 THE DISTRIBUTION OF BLOOD FLOW ALONG THE SMALL INTESTINE OF THE DOG. (Eng.) Eade,
N.; Ginn, R. W. (Sch. Medicine, Auckland Univ.,
ckland, New Zealand). *Proc. Soc. Exp. Biol. Med.*
7(3):390-392; 1978.

investigate whether a blood flow gradient exists
ong the small intestine of the dog, intestinal
ood flow was measured by the indicator-frac-
onation technique with ^{42}K (15 µCi/kg) as the
dicator in 18 anesthetized mongrel dogs. A two-
y analysis of variance demonstrated a signifi-
nt difference of blood flow in the duodenal, je-
nal, and distal ileal sites ($p<0.01$), and Scheffe
ltiple comparison tests showed that the mean
ood flow in the distal ileum was significantly
wer than in the duodenum ($p<0.05$) or in the je-
num ($p<0.05$). There was no significant differ-
ce in blood flow between the duodenum and je-
num. In eight studies in which jejuno-ileal blood
ow was measured, it was significantly higher than
flow in the distal ileum ($p<0.01$) and somewhat
wer than the flow in the duodenum or jejunum. The
n intestinal blood flow to all sites was signi-
antly higher ($p<0.05$) in animals with cardiac
put >10 ml/min/100 g (i.e., in the 7 dogs with-
laparotomy). The results indicate that, when
estinal blood flow is measured under basal con-
ions in the dog, there is a definite gradient
blood flow down the intestine.

0 MICROLYMPHANGIOGRAPHIC STUDY OF LYMPHATIC REGENERATION FOLLOWING INTESTINAL ANAS-
OSIS. (Eng.) Satomura, K.; Tanigawa, N.; Magari, S. (Sch. Medicine, Kyoto Univ., Kyoto, Japan). *Surg. Gynecol. Obstet.* 146(3):415-418; 1978.

Lymphatic regeneration of the canine intestinal lymphatic system was studied following a single-layer inverting ileal anastomosis using a microlymphangiographic technique in which differentiation between lymphatic and blood vessels was assured by washing out the intravascular dye with a saline perfusion solution. Specimens were prepared for light microscopic examination. The central lymphatics in the mucosa of the ileum were readily identified at the center of villi, there was a horizontal lymphatic network at the bottom of the villi, and some branches of it entered the muscularis mucosa, forming a second horizontal network that spread to the bottom of the intestinal glands. Branches of this plexus entered into the submucosa, where the lymphatic vessels were characterized by their large diameters and were associated in a loose plexus with paired arteries and veins, the three vessels running along together. These lymphatics entered the subserosa and received additional branches from a dense tangential plexus located between the circular and longitudinal muscle layers. On the fourth postoperative day, the lymphatics were still interrupted close to the anastomotic line. On the seventh postoperative day, cross circulation of the lymphatics was recognized, and the transverse lymphatics were dilated and apparent; these findings persisted on days 10 and 14. On the 21st day, the normal lymphatic vessel pattern was restored: fine, relatively straight vessels appeared across the anastomotic line.

6761 THE SIGNIFICANCE OF ELEVATED PERITONEAL FLUID PHOSPHATE LEVEL IN INTESTINAL INFARCTION. (Eng.) Sawer, B. A.; Jamieson, W. G.; Durand, D. (Victoria Hosp., London, Ontario, Canada). *Surg. Gynecol. Obstet.* 146(1):43-45; 1978.

A previously described model of intestinal infarction was used to duplicate the original experiment, which demonstrated a significant rise in the serum inorganic phosphate level, and to study the composition of peritoneal fluid. The superior mesenteric artery was doubly ligated at its origin in 10 dogs, and the superior mesenteric vein was tied as it joins the portal vein in another 10. Controls underwent laparotomy with dissection of the superior mesenteric artery or vein. There was a significant increase in the inorganic phosphate level in the peritoneal fluid in all experimental dogs ($p<0.05$), by 2 hr postligation in the superior mesenteric vein-ligated group and by 4 hr in the superior mesenteric artery-ligated group. At 2 hr, the mean levels in the artery- and vein-ligated groups were 6.0 ± 0.56 mg% and 8.1 ± 0.71 mg%, resp. ($p<0.05$). This difference was also seen at 4 hr. Significantly higher ($p<0.05$) serum levels of inorganic phosphate and base deficit were also seen in the experimental groups. These results confirm those of the previous study and show that the inorganic phosphate level in the peritoneal fluid is elevated in addition to that in the serum. The authors suggest that, in the patient with possible intestinal infarction, an elevated serum phosphate level, elevated peritoneal fluid phosphate level, greater base deficit, and leukocytosis may be useful in making an earlier diagnosis of this disease, thereby reducing its morbidity and mortality.

6762 COMPARISON OF RADIO-OPAQUE PELLETS AND CHROMIUM SESQUIOXIDE AS INERT MARKERS IN STUDIES REQUIRING ACCURATE FAECAL COLLECTIONS. (Eng.) Branch, W. J.; Cummings, J. H. (MRC Dunn Nutrition Unit, Cambridge, England). *Gut* 19(5):371-376; 1978.

Radiopaque pellets (ROP) similar to those currently used to measure gastrointestinal transit time were compared with chromium sesquioxide to assess their suitability for use as inert markers in the gut. Five healthy subjects took both markers with every meal for two separate 3-week periods while taking metabolically controlled diets. Overall recovery of both markers was satisfactory; ROP was 99.7 ± 0.3% recovered and chromium, 97.8 ± 1.6%. A comparison of the amount of each marker recovered in 69 separate fecal collection periods of various lengths showed close agreement ($r=0.99$), and the tail-off in marker excretion after cessation of ROP and chromium intake was similar, although slightly more prolonged for chromium. The amount of marker retained in the gut was 13.5% greater for chromium at the end of the 3-week study periods. Both markers proved to be satisfactory for correcting variations in fecal calcium output. The ROP, however, offer clear advantages over chromium in that they are considerably easier and quicker to measure, the method of measurement using x-rays does not alter the stools, and fecal handling is minimized. The precision of ROP measurement is greater and, because of the variety of ROP available, they offer more flexibility for metabolic studies. In addition, stool by stool analysis is possible, enabling simultaneous measurement of mean transit time to be made in experimental subjects.

6763 THE DISINTEGRATION OF SURGICAL SUTURES ON EXPOSURE TO PANCREATIC JUICE. (Eng.) Mizuma, K.; Lee, P. C.; Howard, J. M. (Medical Coll. Ohio at Toledo, P.O. Box 6190, Toledo, OH 43614). *Ann. Surg.* 186(6):718-722; 1977.

DIAGNOSTIC PROCEDURES

6770 ULTRASONIC FINDINGS IN INTRAMURAL EXOGASTRIC LESIONS. (Eng.) Sandler, M. A.; Ratanaprakarn, S.; Madrazo, B. L. (Henry Ford Hosp., 2799 West Grand Blvd., Detroit, MI 48202). *Radiology* 128(1):189-192; 1978.

The cases of four patients with intramural exogastric masses in whom ultrasonic findings suggested a gastric origin are presented. In all cases, a large mass was identified in the left mid- and upper abdomen with a strip of solid tissue extending toward the left hemidiaphragm anteriorly, adjacent to the left lobe of the liver. This finding, best demonstrated on longitudinal scanning, suggested that the mass originated in the stomach, rather than in the spleen or splenic flexure of the colon, which are posterior in location. Two lesions were leiomyoblastomas and two leiomyosarcomas. A benign leiomyoblastoma in one patient contained a small number of echoes of low intensity, while a malignant leiomyoblastoma contained a very large number of high-intensity echoes. This difference could have been due to the necrosis in the malignant lesion providing numerous interfaces between tissues with substantially different acoustic impedance properties, in contrast with the cellular uniformity of the benign lesion. The ultrasound examination in both patients with leiomyosarcoma demonstrated a solid mass with many high-amplitude echoes similar in appearance to the malignant leiomyoblastoma. In the patient with the malignant leiomyoblastoma, the gastric origin of the mass was not considered until the ultrasound examination was carried out. This examination may suggest that a lesion is of gastric origin, and the patient's evaluation may be expedited.

6771 BARIUM ENEMA: AN OUTPATIENT PROCEDURE IN THE EARLY DIAGNOSIS OF ACUTE APPENDICITIS. (Eng.) Lewin, G. A.; Mikity, V.; Wingert, W. A. (Univ. Southern California Sch. Medicine, 1129 North State St., Rm. 1D36A, Los Angeles, CA 90033). *J. Pediatr.* 92(3):451-453; 1978.

The diagnostic value of barium enema as an outpatient procedure was evaluated in 50 children (ages 1-18 yr) to improve the early detection of appendicitis and to reduce both unnecessary resection and morbidity due to perforation. The procedure was performed on an emergency basis without bowel preparation when routine history, physical findings, laboratory data, and roentgenograms were equivocal. Fluoroscopic control and gravity technique not exceeding a height of 90 cm were used; spot films and pre- and postevacuation films were taken, and a specific effort was made to fill the appendix by changing the patient's position. The criteria of Soter and Schey were used for diagnosis. Of 49 successful barium enemas, 36 were normal, 12 were positive, and there was 1 nonfilling appendix. Follow-up was done on 30 normal patients and the 1 with nonfilling appendix, and no sequelae were observed; 6 girls with normal findings were treated for pelvic inflammatory disease (5) or ovarian cyst (1). The positive studies expedited definitive therapy, and were 100% selective for disease requiring surgery; no morbidity from unnecessary surgery occurred. The procedure is recommended particularly in preschool-age children, the obese, the teenage girl with right lower quadrant pain, and in children with chronic diseases in whom an early correct diagnosis is extremely important.

6772 NEW TECHNIQUE OF EXOCRINE PANCREATIC FUNCTION TESTING WITH THE USE OF 4-(N-ACETYL-L-TYROSYL)AMINOBENZOIC ACID. (Cze.) Malis, F.; Fric, P.; Kasafirek, E.; Slaby, J. (II. vedecke oddeleni gastroenterologicke fakulty vseobecneho lekarstvi, Universita Karlova, Karlovo nam. 32, 121 11 Praha 2, Czechoslovakia). *Cas. Lek. Cesk.* 116 (48):1489-1493; 1977.

A 2-g oral dose of 4-(acetyl-L-tyrosyl)aminobenzoic acid was used to assay pancreatic chymotrypsin secretion following stimulation by Lundh's test meal in 45 subjects, including normal controls. Under the action of chymotrypsin, 4-aminobenzoic acid is released in the intestine, and its urinary excretion indicates the degree of exocrine pancreatic secretion. The urinary 4-aminobenzoic acid level is determined by the diazo reaction following acid hydrolysis. The average 4-aminobenzoic acid level found in 8-hr urine samples of healthy controls was 69.4 ± 3% with the lower standard limit of 49.6%. The average 4-aminobenzoic acid level was markedly lower in patients with pancreatic insufficiency (25.1 ± 3.6%). Reduction of the urine collection period to 6 hr was permissible for patients with advanced pancreatic insufficiency. Patients with sprue require an 8-hr urine collection period. The new test is also suitable for outpatient screening.

6773 RADIOIMMUNOASSAY OF LACTOFERRIN IN PANCREATIC JUICE AS A TEST FOR PANCREATIC DISEASES. (Eng.) Fedail, S. S.; Harvey, R. F.; Salmon P. R.; Read, A. E. (Bristol Royal Infirmary, Bristol England). *Lancet* 1(8067):181-182; 1978.

A radioimmunoassay for lactoferrin (LF) was developed to assess the possibility that the measurement of LF in pancreatic juice obtained endoscopically might be helpful in the diagnosis of pancreatic diseases. Pancreatic juice was obtained from 19 patients with chronic pancreatitis and 10 with cancer of the pancreas and from 11 controls. Median LF concentrations were 2,310 ng/ml (range 870-11,400 in patients with chronic pancreatitis compared with 128 ng/ml (range 30-390) in controls and 105 ng/ml (range 10-387) in patients with pancreatic cancer. In one patient with both cancer and pre-existing pancreatitis (for 16 yr), the LF concentration was high (1,300 ng/ml). The results suggest that measurement of lactoferrin in pure pancreatic juice may be useful in the diagnosis of pancreatic disease, especially in the differential diagnosis between cancer and pancreatitis.

6774 ANGIOGRAPHY OF THE PANCREAS. (Eng.) Ekelund, L.; Gerlock, J. (Vanderbilt Univ. Hosp., Nashville, TN 37232). *South. Med. J.* 71(2):173-176; 1978.

The diagnostic potentials of pancreatic angiography are discussed on the basis of four illustrative cases and a review of the literature. The approach must be adjusted to each individual patient, and the examination must proceed until malignancy is confirmed or eliminated. Both the celiac and superior mesenteric arteries must be examined, superselective catheterization of the gastroduodenal or dorsal pancreatic artery should always be attempted, and pharmacoangiography is sometimes helpful in enhancing visualization of the small pancreatic vessels. A normal pancreaticogram in a 40-yr-old man is presented. Pancreaticography revealed discrete, serpiginous encasement of small arteries in the head of the pancreas in a 56-yr-old man; percutaneous transhepatic cholangiography demonstrated obstruction of the common bile duct at this level, and at operation a resectable 2 x 2 cm carcinoma was found. In a 60-yr-old man, angiography indicated a mass in the body and tail of the pancreas, occlusion of the splenic vein with collateral formation, and obstruction at the junction of the superior mesenteric and portal veins. The diagnosis of large, nonresectable carcinoma was confirmed at operation. In a 30-yr-old woman, angiography failed to reveal tumor vessels, and all veins were seen to be normal. A possible expansile lesion in the head of the pancreas was suggested and at operation, a small inflammatory mass was found. Irregular encasement of arteries is the most reliable angiographic finding in the diagnosis of pancreatic carcinoma, the incidence of tumor vessels in these lesions is a debated subject, and the demonstration of venous lesions is very important in the diagnosis.

6775 THE EFFECT OF GASTROGRAFIN AND GLUCAGON ON CT SCANNING OF THE PANCREAS: A BLIND CLINICAL TRIAL. (Eng.) Moss, A. A.; Kressel, H. Y.; Korobkin, M.; Goldberg, H. I.; Rohlfing, B. M.; Brasch, R. C. (Univ. California Sch. Medicine, San Francisco, CA). *Radiology* 126(3):711-714; 1978.

To overcome certain problems that reduce the information content of computed tomographic (CT) scans of the abdomen, a blind clinical trial of the effects of Gastrografin and glucagon on pancreatic CT scanning was carried out in 25 patients who had not had gastric surgery. Following an initial scan, the patients were given dilute Gastrografin (10 ml/230 ml water) to drink and placed on their right sides for 5 min. After being repositioned for scanning in the supine position, glucagon (1 mg over 1 min, i.v.) was given to each patient. The pancreatic region was then rescanned. The series of scans were randomly coded and rated by four radiologists skilled in CT interpretation. Rating for overall pancreatic visualization, visualization of the pancreatic head, body, and tail, and the presence of gas artifacts was performed on a scale of 0 to 4, and the data were statistically analyzed. A significant improvement in visualization of all parts of the pancreas and a reduction in gas artifacts were found following Gastrografin and glucagon administration ($p<0.005-0.02$ for the pooled ratings of the 4 raters). There was a high level of correlation ($r=0.56-0.76$) among the independent ratings performed. Gastrografin-glucagon administration is recommended prior to pancreatic CT scanning if the scanning cycle is 18 sec or longer.

6776 ENDOSCOPY-RELATED BACTEREMIA. (Eng.) Stray, N.; Midtvedt, T.; Valnes, K.; Rosseland, A.; Pytte, R.; Hovik, B. (Central Hosp. Akershus, Oslo, Norway). *Scand. J. Gastroenterol.* 13(3):345-347; 1978.

To determine the risk of bacteremia in patients undergoing endoscopic retrograde cholangiopancreatography (ERCP), a prospective study of 100 patients undergoing gastroscopy, 25 undergoing colonoscopy, and 25 undergoing ERCP was undertaken. The patients were unselected except that none had received antibiotics for 4 days before the procedure, none was febrile, and none had i.v. or urinary bladder catheters. Blood sampling was performed from an antebrachial vein. Bacteremia was detected in 1/100, 1/25, and 0/25 patients subjected to gastroscopy, coloscopy, and ERCP, resp. In 4/600 blood cultures performed, the bacilli recovered appeared to be due to contamination. The results suggest that bacteremia is very rare after endoscopy of the gastrointestinal tract. Therefore, routine prophylactic antimicrobials are not advocated for patients undergoing endoscopic procedures.

6777 USE OF ERCP IN THE DIAGNOSIS OF INTERNAL PANCREATIC FISTULA. (Eng.) Sottomayor, M.; Nom Chong, R.; Dawson, M. (Baragwanath Hosp., P.O. Bertsham, Johannesburg, South Africa). *Gut* 19(3):244-246; 1978.

Two cases of pancreatic ascites in which internal pancreatic fistulae were demonstrated preoperatively using endoscopic retrograde pancreatography (ERCP) are described. The patients, a 31-yr-old man and a 42-yr-old woman, presented with abdominal distention and weight loss. Both had a history of heavy alcohol consumption. Despite paracentesis, ascites accumulated rapidly. ERCP showed features of chronic pancreatitis in both patients and a leak of contrast media from the pancreatic tail into the ascitic fluid in the first patient and from a ruptured pseudocyst into the lesser sac in the second. ERCP is an effective diagnostic technique and may be useful in planning the best method of treatment.

6778 COMPUTED TOMOGRAPHIC SCANNING IN LIVER DISEASE. (Eng.) Fawcitt, R. A.; Forbes, W. C.; Isherwood, I.; Morris, A. I.; Marsh, M. N.; Turnberg, L. A. (Dept. Diagnostic Radiology, Univ.

Manchester, M13 9PT, England). *Clin. Radiol.* 29(3): 251-254; 1978.

The value of computed tomography (CT) in the diagnosis of liver diseases was assessed in 100 patients with liver diseases (23 with jaundice, 40 with cirrhosis, 7 with fatty infiltration, 10 with malignancy, 15 with acute and chronic active hepatitis, and 17 with miscellaneous liver diseases). Of the 23 jaundiced patients, 14 had extrahepatic biliary obstruction, in 13 of which a dilated duct system was demonstrated. The cause of the obstruction was demonstrated by CT in 11 cases. In the nine cases of intrahepatic jaundice, a normal duct system was reported in eight. Reduced liver volume was observed by CT in 14 of 33 cases of nonhemochromatotic cirrhosis and in 4 of 7 cases of cirrhosis with hemochromatosis. CT was diagnostic of fatty infiltration in five of the seven cases. Hepatic metastases were correctly interpreted in six of eight patients, where they were seen as localized areas of diminished density. Eleven patients with chronic active hepatitis were examined, and in the six without marked cirrhotic change, nonspecific abnormalities such as hepatomegaly or hepatosplenomegaly were found. Two of four patients with acute hepatitis had normal scans, and the other two showed hepatic or splenic enlargement. The results show that CT is valuable in the diagnosis of hepatic and biliary tract diseases. Further refinement of hepatic density analysis promises to increase the diagnostic value of CT in cirrhosis.

6779 DIAGNOSTIC ACCURACY OF CT IN CIRCUMSCRIPT LIVER DISEASE.

(Eng.) Scherer, U.; Rothe, R.; Eisenberg, J.; Schildberg, F. W.; Meister, P.; Lissner, J. (Universitat Munchen Klinikum Grosshadern, Marchioninistrasse 15, 8000 Munchen 70, W. Germany). *Am. J. Roentgenol.* 130(4):711-714; 1978.

To evaluate the accuracy of computed tomography (CT) in diagnosing circumscript liver disease, CT findings in 105 patients, usually referred for presumed liver disease but sometimes for suspected pancreatic disease, suspected retroperitoneal lymphomas, or known circumscript liver disease, were compared with the results of invasive diagnostic procedures (51 laparoscopies, 46 laparotomies, and 20 autopsies with at least one procedure performed in each patient). The mean and maximum intervals between the CT scans and invasive procedures were 12.5 and 73 days, resp. All scans were read twice: at the time of the study and retrospectively without knowledge of the results of the invasive procedures, and the data are based on the retrospective evaluation. The invasive methods demonstrated circumscript liver disease in 45/105 patients. In cases of adenoma (1), simple cysts (2), polycystic disease (3), abscesses (2), and echinococciasis (1), the CT diagnosis was correct. In the one case of eosinophilic infiltrations and the one of cholangioma, CT disclosed multiple small areas of decreased density, but a type-specific diagnosis could not be made. In 28/31 cases of metastatic liver disease, the CT diagnosis was correct; 3 cases were misinterpreted as normal. Two of three cases of carcinoma were accurately diagnosed by CT, and one was misinterpreted as hepatosplenomegaly. One case of hemangioma was misinterpreted as normal. There were 6 false-positive diagnoses among the 60 patients without circumscript liver disease: 4 diagnoses of suspicion of metastatic liver disease, 1 misinterpretation of a basal pleural effusion as a large intrahepatic cyst, and 1 diagnosis of a small intrahepatic cyst that did not reach the surface of the liver (although classified as a false-positive, it might be accurate, as laparoscopy only, and not biopsy, was performed). CT is valuable in detecting and differentiating circumscript liver disease. The diagnostic accuracy of CT in diffuse liver disease remains to be established.

6780 DETECTION OF HEPATITIS-B SURFACE ANTIGEN IN BLOOD AND BLOOD PRODUCTS DRIED ON FILTER PAPER.

(Eng.) Farzadegan, H.; Noori, K. H.; Ala, F. (Iranian Natl. Blood Transfusion Service, 138 Villa Ave., Teheran, Iran). *Lancet* 1(8060): 362-363; 1978.

A method for the detection of hepatitis B surface antigen (HBsAg) in blood and blood products dried on filter paper was developed. One drop (>0.025 ml) of capillary whole blood was collected on Whatman 4 filter discs from 10 healthy carriers of HBsAg, and blood obtained by venepuncture from the subjects was processed to obtain packed RBC, plasma, WBC, and platelets. A drop of each of these products and a known HBsAg-positive plasma Cohn fraction-II sample were also put on filter discs. Replicate samples were stored in polyethylene tubes for 1, 3, 7, 14, or 30 days at 4 C or 37 C to simulate various conditions of field study. Then 1, 5, or 10 ml of 0.85% saline solution was added to each tube for 30 min, and the solution was analyzed for HBsAg by immunoelectro-osmophoresis (IEOP), hemagglutination inhibition (HAI), reverse passive hemagglutination (RPHA), and radioimmunoassay (RIA). RIA detected HBsAg in every sample. RPHA was positive in all 1-day samples, in 11/14 7-day samples, and in 7/14 30-day samples. HAI and IEOP were less sensitive, in that order. Dilutions with 1 ml of saline gave the most strongly positive results; 4 C was the best storage temperature. The results suggest that the filter paper technique would have logistic and economic advantages in hepatitis B surveillance programs and would not be associated with a loss of sensitivity or specificity when analyzed by RIA or RPHA.

GASTROINTESTINAL DISEASES

ESOPHAGUS

6808 ESOPHAGEAL ATRESIA WITH DOUBLE TRACHEOESOPHAGEAL FISTULA. (Eng.) Goodwin, C. D.; Ashcraft, K. W.; Holder, T. M.; Johnson, F. R.; Amoury, R. A. (190 Grant St., Dayton, OH 45404). *J. Pediatr. Surg.* 13(3):269-273; 1978.

Four cases of esophageal atresia (EA) with double tracheoesophageal fistula (TEF) are presented, and the relevant literature is reviewed. All patients were boys, weighing 2,735 to 3,150 g. The first patient had an EA and distal TEF, which were treated by dividing the distal fistula and performing a single layer esophagoesophagostomy, using the extrapleural approach. A second TEF was found 9 days later at the C-7 level. In retrospect, the preoperative contrast swallow showed both a proximal and distal TEF. The upper fistula was divided through a transcervical approach. Transient paresis of the right recurrent laryngeal nerve complicated the infant's postoperative course. The second infant was also found to have a second TEF following surgery for EA and distal TEF. This TEF was discovered by esophagoscopy, following the injection of methylene blue into the endotracheal tube. Severe subglottic stenosis and tracheomalacia complicated this patient's course following surgery for the second TEF. A proximal TEF was discovered in the third patient during surgery for EA and distal TEF. Both fistulas were divided, and an esophageal anastomosis was performed under slight tension. He later had a fundoplication for an anastomotic stricture associated with severe gastroesophageal reflux. The last patient had definitive repair for EA and distal TEF delayed until the fourth day of life because of pneumonitis. At operation, the esophagus was in continuity but had a membranous atresia. A large distal TEF was divided, but because the atresia was membranous, the proximal esophagus was not mobilized. Esophagram and bronchoscopy following subsequent repeated episodes of respiratory infections associated with choking while feeding revealed a proximal fistula. A literature review, together with the present cases, suggests that TEF may be more common than is generally recognized and that diagnosis is difficult. During repair of EA and TEF, the proximal esophagus should be mobilized to detect additional TEF. The results of treatment should be good, since this problem occurs in large babies with fewer and less complex associated conditions.

6809 PANETH CELLS IN BARRETT'S ESOPHAGUS. (Eng.) Schreiber, D. S.; Apstein, M.; Hermos, J. A. (West Roxbury Veterans Admin. Hosp., Boston, MA). *Gastroenterology* 74(6):1302-1304; 1978.

Four patients with clinical and endoscopic evidence of inflammation or benign stricture of the esophagus in whom Paneth cells were identified in Barrett's epithelium of the specialized columnar type are reported. The cells were identical to human intestinal Paneth cells by light microscopy, electron microscopy, and histochemical staining reactions. A retrospective review of biopsies from eight additional patients with esophageal specialized columnar epithelium yielded two further cases with Paneth cells. The presence of Paneth cells, along with goblet cells, suggests that specialized columnar epithelium in the esophagus may be a form of highly differentiated intestinalization.

6810 LASER COAGULATION IN ACUTE GASTROINTESTINAL HEMORRHAGE. (Ger.) Kiefhaber, P.; Nath, G.; Moritz, K.; Kreitmair, A. (Medizinische Klinik der Innenstadt der Universitat, Ziemssenstr. 1, D-8000 Munchen 2, W. Germany). *Langenbecks Arch. Chir.* 345:303-306; 1977.

Emergency endoscopic coagulation with a Nd-Yag laser was performed in 198 acute gastrointestinal hemorrhages in 156 unselected patients with recurrent hemorrhages during a 1- to 5-yr period. It was possible to control the hemorrhage in 186 instances, which included 60 massive and protracted hemorrhages from varices of the esophagus, cardia, and stomach; 10 arterial and 4 capillary-venous hemorrhages in Mallory-Weiss syndrome; 57 arterial and 40 venous-capillary hemorrhages from esophageal, gastric, duodenal, and jejunal ulcers; 11 hemorrhages in multiple esophageal and gastric erosions; and 4 arterial and venous hemorrhages from colonic ulcers. Recurrent hemorrhages were seen in 18 patients with varices 3-30 days after laser coagulation; all defects were new. Recurrent hemorrhage from the coagulated defect was seen in only one patient (with Mallory-Weiss syndrome). The findings indicate the great value of endoscopic laser coagulation of gastrointestinal hemorrhage.

6811 GASTROESOPHAGEAL REFLUX IN INFANTS AND CHILDREN: A USEFUL CLASSIFICATION AND RELIABLE PHYSIOLOGIC TECHNIQUE FOR ITS DEMONSTRATION. (Eng.) McCauley, R. G. K.; Darling, D. B.; Leonidas, J. C.; Schwartz, A. M. (New England Medical Center Hosp., 171 Harrison Ave., Boston, MA 02111). *Am. J. Roentgenol.* 130(1):47-50; 1978.

A radiologic method for the demonstration of gastroesophageal reflux in children is described, and a clinically useful system for grading of reflux is presented. Colloidal barium sulfate (100 g in 200 ml water) is administered in a volume similar to a normal meal, and then spot films are taken in the lateral and supine positions to evaluate the swallowing mechanism and the contour and peristalsis of the barium-filled esophagus. Routine fluoroscopy and spot films of the stomach and duodenum are obtained with partial distention of the stomach. Additional barium is given, following which the gastroesophageal junction is examined using intermittent fluoroscopy and small fields and while turning the subject gently from side to side in a supine position. Reflux, if present, will be seen in the majority of cases at this time, and its maximum extent can be recorded. Having the subject suck on a rubber nipple may aid in the demonstration of reflux. In the absence of reflux, hiatal hernia is looked for using thickened barium (75 g/25 ml water). After the subject has sat erect for 30 min, a delayed film is taken in the supine position and should include the lower half of the esophagus. The overall incidence of reflux in 507 patients was 40%; it was 64% among infants <3 months old. Most patients with reflux (70%) were under 1 yr of age. The grading system ranges from reflux into the distal esophagus only (grade 1) to reflux with aspiration into the trachea and lungs (grade 5). This method and system may be useful in understanding the true incidence and significance of gastroesophageal reflux.

6812 ESOPHAGEAL EPITHELIAL RESPONSE TO GASTROESOPHAGEAL REFLUX: A QUANTITATIVE STUDY. (Eng.) Johnson, L. F.; Demeester, T. R.; Haggitt, R. C. (Walter Reed Army Medical Center, Washington, DC 20012). *Am. J. Dig. Dis.* 23(6):498-509; 1978.

To examine the relationship between esophageal mucosal exposure to gastric acid, exposure of the distal esophageal mucosa to gastric juice was quantitated by 24-hr pH monitoring in 100 individuals and was correlated with morphologic data derived from esophageal biopsies. The degree of acid exposure to the distal esophagus (time exposed to pH <4) correlated directly with increases in both relative and absolute length of the subepithelial papillae ($r=0.333$, $p<0.01$ and $r=0.305$, $p<0.01$, resp.) and to relative basal zone hyperplasia ($r=0.261$, $p<0.05$). Both papillary length and basal zone hyperplasia decreased after antireflux surgery had reduced acid exposure to normal in the five patients studied. Reflux in the recumbent position resulted in prolonged exposure of the mucosa to acid because of poor acid clearing from the esophagus. This exposure caused longer papillae than did upright reflux, where there were more frequent reflux episodes, but with rapid acid clearance. The presence of a hiatal hernia was associated with longer papillae, lower distal esophageal sphincter pressure, increased reflux frequency, and prolonged recumbent acid clearance. Twenty-four hour pH monitoring correlated better with papillary length ($r=0.250$, $p<0.05$) than did symptoms or other clinical measures of gastroesophageal reflux. This study shows that the pH of refluxed gastric juice serves as a sensitive tag to assess two important determinants of reflux esophagitis: (a) reflux frequency secondary to incompetency of the cardioesophageal junction and (b) esophageal clearing of the refluxed gastric juice. Both of these components must be assessed in the future in determining benefit from a potential therapeutic measure.

STOMACH

6833 THE ORIGIN OF THE LEFT GASTRIC ARTERY. (Eng.) Naidich, J. B.; Naidich, T. P.; Sprayregen, S.; Hyman, R. A.; Pudlowski, R. M.; Stein, H. L. (North Shore Univ. Hosp., 300 Community Drive, Manhasset, NY 11030). *Radiology* 126(3):623-626; 1978.

To investigate variations in the origin of the left gastric artery (LGA), the origin and visualization of the artery were evaluated retrospectively in 500 consecutive angiograms that included at least one selective study of the celiac trunk or the leinogastric trunk. If there was any doubt about the visualization or origin, the LGA was considered as not visualized. The LGA could not be identified in 40 cases. In nine cases, the LGA originated directly from the aorta, and the phrenic artery arose as a branch of the LGA. In one case, the LGA originated from the superior mesenteric artery. In 450 cases, the LGA arose from the celiac or leinogastric trunk, and the orifice was well seen in 378. The orifice was visible in 218/220 patients in whom both anteroposterior and right posterior oblique projections were obtained but in only 160/230 in whom only the anteroposterior projection was obtained. In 373/378 patients, the LGA was a single vessel arising from the celiac or leinogastric trunk anywhere between its origin and its bifurcation into the hepatic and splenic arteries; in 1, the LGA arose from the splenic artery; in 2, it arose from the hepatic artery; and in 2 patients, 2 LGAs of almost equal caliber arose from the celiac artery. In 102 patients, the LGA supplied both the stomach and the liver to varying extents. Anomalous origin of the LGA can lead to failure to visualize it in arteriograms or to complications in catheterization therapy of gastrointestinal hemorrhage.

6834 DOUBLE CHANNEL PYLORUS. (Eng.) Jamshidnejad, J.; Koehler, R. E.; Narayan, D. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *Am. J. Roentgenol.* 130(6):1047-1050; 1978.

The radiographic and clinical features in five patients with double channel pylorus are presented and compared with those in previously reported cases of this deformity. The patients ranged in age from 64 to 76 yr. The anomaly was confirmed endoscopically in four patients and at surgery in one. All patients had epigastric pain and symptoms consistent with peptic ulcer disease. None exhibited evidence of gastric outlet obstruction. Three patients underwent gastrectomy. The radiographic examination revealed barium outlining two channels connecting the antrum with the base of the duodenal bulb in all cases. A fistulous channel passed through the lesser curvature aspect of the pylorus and entered the superior fornix of the duodenal bulb. The two channels were separated by a bridge or septum. In each case, an ulcer crater was seen along the superior aspect of the prepyloric antrum or duodenal bulb. Since the double channel pylorus was shown not to have been present on prior upper gastrointestinal radiographs or endoscopy in 15 previous and 2 current cases and since most cases occur in older subjects, the lesion is probably an acquired peptic deformity in most instances.

6835 UPPER GASTROINTESTINAL BLEEDING IN THE INTENSIVE CARE UNIT. (Eng.) MacDonald, A. S.; Pyne, D. A.; Freeman, A. N. G.; Holland, S. G.; Badley, B. W. D. (Clinical Res. Center, 5849 University Ave., Halifax, Nova Scotia B3H 1W2, Canada). *Can. J. Surg.* 21(1):81-84; 1978.

The pathogenesis, diagnosis, and treatment of upper gastrointestinal bleeding secondary to conditions requiring intensive care are summarized. The clinical conditions that precede erosive gastritis are shock, sepsis, organ failure (kidney, liver, lung), drug ingestion (acetylsalicylic acid, alcohol, corticosteroids), and elevated intracranial pressure, and in the majority of patients, more than one factor is involved. Those patients that bleed from the erosions are distinguished from those who do not by continuation of the stressful situation that led to the erosions. The mechanisms of these pathogenetic conditions are not entirely clear. Bleeding is the identifying symptom of erosive gastritis; the most important diagnostic tool is fiberoptic endoscopy. Barium contrast roentgenography is not helpful. At endoscopy, early in the illness, one finds numerous punctate areas of hemorrhage, typically most intense along the lesser curvature and over the posterior wall of the fundus. The antrum is often spared, but the duodenum is often involved, sometimes alone. As the illness progresses, the erosions enlarge and coalesce, forming a large serpiginous shallow ulcer, and they may deepen. The drug-precipitated entity responds to simple lavage with ice water and oral antacids. Treatment of other patients has not been consistently successful. The histamine H_2-receptor antagonist, cimetidine, was used in an uncontrolled trial in 27 patients with erosive gastritis; bleeding stopped in 24. Based on clinical experiences with both metiamide and cimetidine, the authors recommend conservative surgery. In those who continue to bleed despite the administration of H_2 blockers, discrete ulcers are present that can be managed by suture ligation or excision, followed by vagotomy and drainage and continuous cimetidine therapy until the stressful situation has passed.

6836 GASTRIC STUMP CANCER: STATISTICAL EVALUATION. (Eng.) Cheli, R.; Molinari, F.; Santi, L.; Ciancamerla, G.; Puntoni, R. (Ospedale Generale Regionale, Viale Benedetto XV, 16132 Genova, Italy). *Rend. Gastroenterol.* 9(3): 169-172; 1977.

To determine the relationship between gastric surgery and the development of gastric stump cancer, the mortality due to cancer and other causes was analyzed in 180 patients who underwent resection for gastric ulcer and 337 patients who underwent resection for duodenal ulcer. The mortality rate for gastric stump cancer was 2% in the patients who underwent resection for duodenal ulcer and 5% for those who underwent surgery for gastric ulcer. A statistical analysis showed a highly significant increase ($p<0.001$) in mortality, in relation to the total population of Genoa, for gastric stump cancer in both groups. There was also a significantly higher ($p<0.005$) mortality from extragastric tumors among the patients who underwent surgery for ulcer than in the general population.

6837 PLASMACYTOMA OF THE STOMACH. (Eng.) Scott, F. E. T.; Dupont, P. A.; Webb, J. (Wexham Park Hosp., Slough, Berkshire, England). *Cancer* 41(2):675-681; 1978.

Three cases of undoubted plasma cell tumor of the stomach that had been diagnosed histologically were re-examined by the immunoperoxidase (IP) staining technique to confirm the diagnosis by demonstrating a single type of immunoglobulin in the tumor cell using formalin-fixed, paraffin-embedded tissue from the original biopsies. The detailed case reports are presented. Sections of benign plasma cell granuloma were used as a nonspecific positive control. One patient with a tumor that was confined to the stomach and one in whom a palliative partial gastrectomy had been performed for the removal of a large tumor of the distal third of the stomach with extensive lymphatic but no skeletal involvement had tumor cells that stained eavily with the IP technique, revealing high conentration of Russell bodies that contained exlusively IgG heavy chains and K-type light chains. lood and urine specimens from the second patient ad shown no excess of a single immunoglobulin type. P staining of tissue from a patient with plasmaytoma of the stomach in which a dense mass of alignant plasma cells extended completely through he muscle layer and in whom skeletal involvement ccurred 2 yr after resection revealed exclusively gA heavy chains and K-type light chains but no ussell bodies. Sixty-six cases of primary gastric umor reported in the literature are reviewed, and he pathology of plasma cell tumors is discussed. he demonstration of intracellular immunoglobulins ermits a firm distinction to be made between true lasma cell tumors and reactive plasma cell granuomas on the one hand and the other types of maligant lymphoma on the other.

838 ACUTE GASTRIC DILATATION IN NEGLECTED CHILDREN. (Eng.) Franken, E. A.; Fox, .; Smith, J. A.; Smith, W. L. (Indiana Univ. Medial Center, 1100 West Michigan St., Indianapolis, N 46202). *Am. J. Roentgenol.* 130(2):297-299; 1978.

cute gastric dilatation as a manifestation of hild neglect and abuse is reported. Acute sudden astric dilatation developed in each of five chilren (ages 2-8 yr) after the ingestion of a large eal. The height and weight of all patients were elow the third percentile, and all had "voracious" r "huge" appetites, and historic evidence of deprivation and/or of neglect, and physical abuse. The athogenesis of acute gastric atony in the deprived hild is related to structural and functional changes n the stomach due to chronic starvation. Treatent of the gastric distention involves decompreson of the stomach by nasogastric intubation, apropriate i.v. fluids to counteract shock, and slow esumption of small but frequent p.o. feedings after 2-24 hr. Radiographic recognition of acute gastric ilatation in a child who is not postoperative or ntoxicated should suggest the presence of chronic tarvation and child neglect. Prevention of further eglect requires social management of the entire amily.

839 THE FURTHER INVESTIGATION ON THE GASTRIC ACID SECRETION IN THE PRIMARY HYPERPARAHYROIDISM. (Eng.) Segawa, K.; Nakazawa, S.; aito, Y.; Imai, K.; Yamase, H.; Yamada, K.; *et al.* Nagoya Univ. Sch. Medicine, Tsuruma-cho, Showa-ku, agoya, 466 Japan). *Gastroenterol. Jpn.* 12(5):347-51; 1977.

astric output was studied in 11 patients with hyerparathyroidism before and 10-114 days after arathyroidectomy to further investigate the relationship between serum calcium level on one hand and serum gastrin level and gastric secretion on the other. The serum calcium level fell significantly after the operation (from 5.96 ± 0.18 mEq/l to 4.19 ± 0.17 mEq/l, $p<0.001$). The serum gastrin level, basal gastric output (BAO), and maximal gastric output (MAO) also decreased significantly after operation (from 167.00 ± 7.08 to 73.40 ± 24.21 pg/ml, from 1.74 ± 0.64 to 0.42 ± 0.26 mEq/hr, and from 5.66 ± 2.29 to 2.13 ± 1.45 mEq/hr, resp., $p<0.05$, $p<0.001$, and $p<0.02$, resp.). Serum alkaline phosphatase (AP) activity appeared to be an indicator of the duration of the disease, rising with longer durations. In patients with AP activity >20 Kind-King (KK) U, BAO and MAO were 1.00 ± 0.55 and 4.86 ± 2.46 mEq/hr, resp.; in patients with AP activity <20 KKU, BAO and MAO were 1.87 ± 0.97 and 8.43 ± 3.43 mEq/hr, resp. In five of the patients, the BAO and MAO were measured a second time between 67 and 391 days after the first postoperative study; both values had increased compared with the first study results, and both approached preoperative values. The authors postulate that the adaptation of the parietal cell to hypercalcemia prior to operation (i.e., producing normal gastric secretion levels despite the elevated stimulus) leads to decreased secretion after operation because of the lowered serum calcium level and then as the parietal cells readapt over time to the new level of serum calcium, the gastric secretion increases to normal.

6840 RECURRING HYPERPLASTIC GASTRIC POLYPS FOLLOWING SUBTOTAL GASTRECTOMY. (Eng.) Joffe, N.; Goldman, H.; Antonioli, D. A. (Harvard Medical Sch., 300 Brookline Ave., Boston, MA 02215). *Am. J. Roentgenol.* 130(2):301-305; 1978.

The clinical, radiologic, and pathologic findings in two cases of recurring symptomatic hyperplastic gastric polyps after subtotal gastrectomy are presented. In a 30-yr-old woman, the initial surgery was undertaken for treatment of peptic ulcer disease. In a 34-yr-old woman, a patient with known pernicious anemia, the indication for surgery was multiple antral polyps. Within 2 yr after surgery, both patients developed multiple hyperplastic polyps in the gastric remnant. Repeated endoscopic and barium examinations over a 7- to 8-yr period revealed a progressive increase in the size and number of these polyps with formation of large conglomerate masses in the gastric remnant immediately proximal to the gastrojejunostomy stoma. Surgical or transendoscopic removal of the polyps was indicated by severe symptoms on several occasions: the first patient experienced intermittent epigastric pain, vomiting, and gastrointestinal hemorrhage; during one episode of severe vomiting, an entire polyp was ejected; and the second patient had symptoms of intermittent gastric outlet obstruction produced by prolapse of a large polyp through the stoma into the jejunum. It is proposed that reflux bile gastritis may have played an important etiologic role in the development of these recurring hyperplastic polyps.

6841 ELECTRON MICROSCOPIC OBSERVATIONS IN INFANTILE HYPERTROPHIC PYLORIC STENOSIS (IHPS). (Eng.) Jona, J. Z. (411 East Mason St., Milwaukee, WI 53202). *J. Pediatr. Surg.* 13(1): 17-20; 1978.

The ultrastructural appearance of the parasympathetic ganglia, the supporting interstitial cells, and smooth muscles in infantile hypertrophic pyloric stenosis (IHPS) is summarized. Tissue obtained at pyloromyotomy from five infants (ages 3-5 weeks) with typical clinical, radiologic, and operative findings of IHPS and from 2-week-old infant rabbits, adult rabbits, and rats was prepared for electron microscopic examination. In all, 35 plexuses of human origin were studied in this material, and the animal material permitted evaluation of the morphology and maturation changes in the pyloric ganglia. On the whole, no abnormalities were found in the neurons or interstitial cells of the infants. Occasionally (<10% of the total), a very large axon was observed, measuring 2-3 times the diameter of normal large axons. Intrinsic derangement of the organelles and axolemma of these axons was seen. The cytoplasm of the supporting cells contained small filaments and radiating processes that enveloped a group of axons or part of the neuron's surface. There was a marked increase in the overall thickness of the circular smooth muscles of the pylorus. The animal control material resembled the human material in most respects. The small, immature ganglia in the infant rabbits, which resembled those in the babies, disappeared in the older animals, suggesting that the maturation process followed a normal course in babies with IHPS. It is concluded that degenerative changes or failure of maturation of the ganglia cannot account for the clinical syndrome of IHPS.

6842 CONGENITAL HYPERTROPHIC PYLORIC STENOSIS: THE ROLE OF GASTRIN REEVALUATED. (Eng.) Werlin, S. L.; Grand, R. J.; Drum, D. E. (Children's Hosp. Medical Center, 300 Longwood Ave., Boston, MA 02115). *Pediatrics* 61(6):883-885; 1978.

To evaluate the potential role of gastrin in the etiology of congenital hypertrophic pyloric stenosis, serum gastrin levels were measured in cord blood of affected infants, matched controls, and mothers of both. Cord and maternal sera were available from 40 of the 51 maternal-infant pairs in which pyloric stenosis developed in the infant in a study of 59,508 pregnancies. No differences were identified when values from infants with pyloric stenosis were compared with those from control infants (117 ± 10 and 115 ± 8 pg/ml, resp.). The mean cord serum gastrin level of all infants (116 ± 9 pg/ml) was significantly greater than the mean maternal gastrin level (93 ± 8 pg/ml, $p<0.001$). The data effectively dismiss the possibility that elevated serum gastrin concentration in mother or infant at the time of delivery can be implicated as a cause of congenital pyloric stenosis.

6843 TRIMIPRAMINE IN THE TREATMENT OF GASTRIC ULCER. (Eng.) Valnes, K.; Myren, J.; Qvigstad, T. (Ulleval Hosp., Oslo, Norway). *Scand. J. Gastroenterol.* 13(4):497-500; 1978.

A double-blind study comparing trimipramine with placebo during 4 weeks of treatment was carried out in 40 patients with confirmed gastric ulcers. The daily dose of trimipramine was 50 mg p.o. given at bedtime. No serious side-effects occurred. After 4 weeks of treatment, endoscopy showed that 12 of the 20 patients receiving trimipramine had completely healed ulcers, while only 4 of the 20 ulcers in the patients who received placebo were healed ($p=0.025$). A significant improvement in the patients' assessment of the results of treatment (i.e., better, unchanged, or worse) was also observed in the patients receiving trimipramine ($p=0.025$). It is assumed that the previously reported antisecretory effect of the drug, together with its sedative and anti-depressant effect, make trimipramine valuable in the treatment of peptic ulcer disease.

6844 GASTRODUODENAL ULCERATION IN RENAL TRANSPLANT PATIENTS. (Eng.) Schweizer, R. T.; Bartus, S. A. (Hartford Hosp., Hartford, CT 06115). *Conn. Med.* 42(2):85-88; 1978.

Gastroduodenal ulceration was reviewed retrospectively in 200 consecutive renal transplant patients, and a prospective study of this entity was undertaken (113 patients enrolled to date) to determine whether antacid therapy and prophylactic gastric surgery can reduce the incidence and severity of this complication. The 200 patients received antacid therapy as often as every hour during the day, concomitant with large doses of steroids and every 2 hr at night. Prophylactic surgery (usually vagotomy and pyloroplasty) were performed in all patients who had a documented duodenal or gastric ulcer prior to receiving the kidney transplant. The patients in the prospective study were similarly treated. Of the 200 patients, 25 developed upper gastrointestinal ulceration following renal transplant, 12 of the 25 had significant hemorrhage, and 2 of the 12 died; all had had infrequent antacid therapy for various reasons preceding the bleeding episode, 9/12 had received very large corticosteroid doses for rejection episodes, and 2/12 had previously undisclosed histories of previous ulcer disease. Of the remaining 13/25 patients, 1 required plication for perforation of a gastric ulcer, and the others responded to increased antacid therapy plus decreased corticosteroid dosage. Of the 113 patients, 9 required treatment for gastrointestinal ulceration (vagotomy and pyloroplasty in 5; vagotomy and antrectomy in 1; plication and then gastrectomy in 1; plication, vagotomy, and pyloroplasty in 1; and cimetidine therapy in 1); all 9 patients lost their transplants. The greatest risk of ulceration appears to occur when the prednisone maintenance dose is >60 mg/day. The incidence of gastrointestinal ulceration can be kept at a minimum through the use of prophylactic surger and antacid administration; preventive measures and aggressive therapy are also important factors in achieving a low mortality.

6845 PREPYLORIC GASTRIC ANTRAL WEB: A PUZZLING EPIDEMIC. (Eng.) Bell, M. J.;

ernberg, J. L.; Keating, J. P.; Moedjona, S.;
cAlister, W.; Shackelford, G. D. (St. Louis Chil-
ren's Hosp., 500 South Kingshighway, St. Louis,
O 63110). *J. Pediatr. Surg.* 13(3):307-313; 1978.

he spectrum of manifestations and appropriate
herapy were studied in an unusual clustering of
8 infants and children in whom a radiographic diag-
osis of antral web was made during a 26-month
eriod. Nonbilious, often projectile vomiting
as the predominant presenting symptom in 24 in-
ants who were less than 6 months of age. The
lder children complained of pain, vomiting, full-
ess after eating, and eructation. The charac-
eristic radiologic finding was a wire-like trans-
erse septum 1-2 cm proximal to the pylorus. Poor
ntral filling was an important early clue in the
adiographic search for the webs. Pyloroplasty
as performed in 20 patients, frequently after
ailure of medical management of symptoms. Co-
xistent congenital abnormalities were present in
28% of patients. A search for environmental and
amilial factors has failed to elucidate any tera-
ogenic influences in this population.

STOMACH

Peptic Ulcers

6897 CIMETIDINE FOR ULCERS RECURRING AFTER GASTRIC SURGERY. (Eng.) Hoare, A. M.; Jones, E. L.; Hawkins, C. F. (Queen Elizabeth Hosp., Birmingham B15 2TH, England). *Br. Med. J.* 1(6123): 1325-1326; 1978.

The effect of cimetidine therapy was studied in 20 patients with recurrent ulcers following gastric surgery, to discover if this drug will encourage healing of these ulcers even if the acid output is low. Before treatment, the mean peak acid output was 23.4 mmol/hr; five patients had a peak output of less than 10 mmol/hr and three less than 2.5 mmol/hr. Endoscopy was carried out before and after 6 weeks of cimetidine therapy (200 mg t.i.d. with meals and 400 mg at night). Endoscopy was repeated after a further 6 weeks of treatment if the ulcer had not healed during the first 6 weeks. After 6 weeks, 17 ulcers had healed, and after 12 weeks, 19 had healed. The results suggest that cimetidine aids in ulcer healing, even if the acid output is low.

6898 CIMETIDINE FOR RECURRENT ULCER AFTER VAGOTOMY OR GASTRECTOMY: A RANDOMISED CONTROLLED TRIAL. (Eng.) Kennedy, T.; Spencer, A. (Royal Victoria Hosp., Belfast BT12 6BA, Northern Ireland). *Br. Med. J.* 1(6122):1242-1243; 1978.

In a randomized controlled trial, 6 weeks of therapy with cimetidine (1 g/day) was compared with placebo in the treatment of recurrent ulcers after gastrectomy or vagotomy for duodenal ulcer. Healing, assessed endoscopically, was seen in 7 of 12 patients given cimetidine and in 5 of 12 controls. Four controls whose ulcers did not heal were subsequently treated with cimetidine, and in two, the ulcers healed after 6 weeks. Pain recorded by the patient and consumption of alkalis were each slightly but not significantly less in the cimetidine-treated patients. When cimetidine is to be used for recurrent ulceration, the dosage and duration of treatment should probably be increased.

SMALL INTESTINE

6919 RADIOLOGICAL MANIFESTATIONS OF SMALL INTESTINAL SOUTH AMERICAN BLASTOMYCOSIS. (Eng.) Avritchir, Y.; Perroni, A. A. (Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Sao Paulo, Brazil). *Radiology* 127(3):607-609; 1978.

The small intestinal radiological findings in three cases of South American blastomycosis (SAB), caused by *Paracoccidioides brasiliensis*, are reported. In a 23-yr-old patient, a barium enema revealed a conical, nondistensible cecum and rigid terminal ileum without ulceration. A second patient had dilatation of the intestinal wall in a small bowel series performed at age 20 yr; 4 yr later, a small intestinal series showed multiple long stenotic areas in the jejunum. A barium enema in a 36-yr-old patient revealed contraction at the cecal tip and a distensible terminal ileum with large, somewhat nodular folds. Thus, the radiologic findings of small intestinal SAB are nonspecific, e.g., fixed narrowing and mucosal irregularities. Differential diagnostic possibilities include regional enteritis, tuberculosis, and lymphoma, but when a patient lives in an endemic area, SAB should also be considered. None of the above three cases was correctly diagnosed before laparotomy, when *P. brasiliensis* was always found. A retrospective review of the postmortem findings of 13 patients with SAB during a 6-yr period revealed 3 patients with involvement of the small intestine, supporting the contention that such involvement is more common than has been previously considered.

6920 HEMORRHAGIC DUODENITIS: CLINICAL PROFILE.

(Eng.) Bartolomeo, R. S.; Frank, H. D.; Taubin, H. L. (222 Station Plaza North, Mineola, NY 11501). *N.Y. State J. Med.* 78(2):212-214; 1978.

The clinical findings in 44 patients with hemorrhagic duodenitis are reviewed in a retrospective study. The mean age at presentation was 49.2 yr, and the major symptoms were melena (52.3%), epigastric pain (47.7%), and hematemesis (45.5%). The most common endoscopic findings were marked hyperemia (65.9%), friability (50%), and active hemorrhage (38.6%). The upper gastrointestinal barium meal findings were interpreted as normal in 75% of the 45 upper gastrointestinal series performed. The remainder had radiographic signs confined to the duodenal bulb, consisting of spasticity and irritability of the bulb or hypertrophied duodenal folds. A history of aspirin or aspirin-containing product ingestion was found in 68% of patients 1 week prior to admission. A history of alcohol ingestion was obtained in 34% 1 week prior to admission. Forty-five percent of the patients required blood transfusions, but only one required surgical intervention because of persistent uncontrolled hemorrhage. The only death was in a patient with Bernard-Soulier platelet disorder, while the other 42 cases responded to conservative medical management. Definitive diagnosis of hemorrhagic duodenitis is dependent on direct endoscopic visualization of the mucosa. Cessation of bleeding is to be expected with conservative management.

6921 MALIGNANT LYMPHOMA AND EXTENSIVE VIRAL WART FORMATION IN A PATIENT WITH INTESTINAL LYMPHANGIECTASIA AND LYMPHOCYTE DEPLETION.

(Eng.) Ward, M.; Small, W. P.; Le Roux, A.; Sircus, W. (Western General Hosp., Edinburgh, Scotland). *Postgrad. Med. J.* 53(1626):753-757; 1977.

The case of a patient who developed peripheral mosaic warts and a malignant small bowel lymphoma in association with marked lymphocyte depletion is presented. The patient developed asymmetrical peripheral edema at the age of 12 yr, extensive viral warts at 18 yr, and intestinal lymphangiectasia at 29 yr. The absolute lymphocyte count was 0.8×10^9/l and serum albumin 27 g/l. A low-fat diet and diuretics brought about complete resolution of edema and restoration of the serum albumin to within the normal range. The lymphocyte count remained low and the warts became more extensive on the hands and feet, but the patient remained otherwise asymptomatic until 10 yr later, when he presented with subacute small bowel obstruction. At laparotomy, chylous ascites was found together with gross thickening and hypomotility of the proximal small bowel. A mid-jejunal tumor had narrowed the lumen, and there was a discrete ulcer proximal to it. Obstruction persisted, despite local resection and radiotherapy. Although the patient finally developed extensive abdominal sepsis with bacteremia and died, the warts almost completely disappeared from his hands. The authors propose that the severity of this patient's lymphocyte depletion may account for the appearance of such gross viral warts and ultimately to the complication of small intestinal lymphoma.

6922 RELATIONSHIP BETWEEN 505 PAIRED LIVER TESTS AND BIOPSIES IN 242 OBESE PATIENTS.

(Eng.) Galambos, J. T.; Wills, C. E. (Emory Univ. Sch. Medicine, 69 Butler St., S.E., Atlanta, GA 30303). *Gastroenterology* 74(6):1191-1195; 1978.

Studies were carried out in 242 obese patients to determine how reliably biopsy and liver function tests can detect liver pathology. Liver tests were obtained at the time of the liver biopsy on 242 occasions before jejunoileal bypass, on 105 occasions within 18 months, and on 158 occasions beyond 18 months of surgery. The biopsies were obtained as part of routine evaluation of these patients. Therefore, the selection of the patient or the timing of the biopsy did not depend on the results of the liver tests. Five hundred five liver biopsies were compared with liver tests that were obtained at the time of the biopsy. The biopsy abnormalities were lobular (similar to alcoholic) hepatitis, fibrosis, portal hepatitis, and steatosis. The liver tests were SGOT, alkaline phosphatase, bilirubin, and albumin determinations. For the purpose of the analysis, the severity of histological abnormalities were defined. Biochemical abnormalities were arbitrarily defined at two levels. Level 1 was the standard definition of normal-abnormal for our laboratories. Level 2 considered liver tests abnormal only when these deviated more markedly from normal to simulate the common clinical practice that requires similar or greater abnormalities to consider a patient for liver biopsy. The data were then analyzed in two ways: (1) to describe how often the liver tests were abnormal (or normal) when the biopsy was abnormal (the denominator was the liver biopsy), and (2) conversely, how often the lesions were present in liver biopsies when the liver tests were normal or abnormal (the denominator was the liver test). In 60% to 89% of the patients with abnormal liver biopsy, one or more of the liver tests were also abnormal. However, in 9 of 12 comparisons (4 types of lesions in the 3 time periods), the frequency of abnormal biopsies was not higher in those who had abnormal liver tests. The more severe liver test abnormalities (level 2) had a better association with biopsy abnormalities. However, such severe deviations from normal were seen in only about 12% of the abnormal liver biopsies. It appears that the liver function tests do not measure the functional capacity of the liver in quantitative terms and are not sufficiently reliable to identify correctly and consistently the presence of four types of histological lesions, at least in obese patients.

6923 RAPID DEVELOPMENT OF MICRONODULAR CIRRHOS FOLLOWING SMALL BOWEL BY-PASS FOR OBESITY A FORM OF IATROGENIC NUTRITIONAL CIRRHOSIS?

(Eng.) Spellberg, M. A.; Bermudez, F. (Michael Reese Hosp. and Medical Center, 2900 S. Ellis Ave., Chicago, IL 60616). *Am. J. Gastroenterol.* 68(4):354-358; 1977.

Progressive fatal liver disease in two nonalcoholic women who underwent small bowel bypass for obesity is reported. The patients died 3 and 8 months after surgery, resp. At autopsy, the morphologic changes were indistinguishable from those seen in alcoholic cirrhosis. Advanced micronodular cirrhosis with extensive fibrosis and necrosis, polymorphonuclear leukocyte infiltration, Mallory bodies, and fatty metamorphosis were present in both cases. It is postulated that the nutritional disturbance, including protein deficiency, and large amounts of fatty acids delivered to the liver from the fat depots, results in fatty metamorphosis, the Mallory bodies, and cirrhosis. Bacterial toxins from the excluded loop of intestine may contribute to this process.

6924 THE EFFECT OF STERCULIA BULK ON THE VISCOSITY OF STOMAL OUTPUT FROM TWELVE PATIENTS WITH ILEOSTOMY. (Eng.) Dalhamn, T.; Graf, W.; Nilsson, L. H. (St. Erik's Hosp., 112 82 Stockholm, Sweden). *Scand. J. Gastroenterol.* 13(4):485-488; 1978.

The effect of a commercial bulk preparation (sterculia bulk) on stomal output, water content, and viscosity was studied in 12 patients with ileostomy. The addition of 15 g of sterculia bulk to the diet daily increased the stomal output, in comparison with a control level, by a mean of 92.6 g ($p<0.01$). Dry weight increased by an average of 14.3 g to 72.2 g/24 hr ($p<0.05$). There was a significant decrease in water content ($p<0.05$). Viscosity of the stomal output increased by about 100% ($p<0.01$). Adding bulk to the diet of ileostomized patients may facilitate the management of the stoma by increasing the viscosity of the output.

6944 RISK OF COELIAC DISEASE IN CHILDREN OF PATIENTS AND EFFECT OF HLA GENOTYPE. (Eng.) Dennis, N. R.; Stokes, C. R. (Children's Hosp., Buffalo, NY 14222). *J. Med. Genet.* 15(1): 20-22; 1978.

Seventy-three offspring of parents with celiac disease were examined to determine the risk to these children of developing the disease and to what extent this risk is affected by the histocompatibility locus antigen HLA-B. There were 40 index patients who were selected because they had at least one child over the age of 1 yr. In 27 index cases, the symptoms began before the age of 12 yr, while in 13 cases, the onset occurred between 21 and 57 yr. The childhood onset patients themselves had 51 children (aged 1-24 yr), of whom 2 had typical childhood celiac disease and 12 were classified as "suspected." Three of the latter had symptoms of celiac disease, and the other nine were selected because of low height or weight for their age. The 13 adult onset index patients had 22 children (aged 3-40 yr), of whom 1 had childhood celiac disease and 2 were classified as suspected. The parents of all four children with confirmed celiac disease were HLA-B8-positive, but one affected child did not inherit his affected parent's B8 antigen. The findings are consistent with the hypothesis that an allele affecting liability to celiac disease is in linkage disequilibrium with HLA-B8.

6945 ORGAN CULTURE OF COELIAC AND NON-COELIAC SMALL INTESTINAL MUCOSA. (Eng.) Stevens, F. M.; Keane, R.; Fottrell, P. F.; McNicholl, B.; McCarthy, C. F. (Regional Hosp. and Univ. Coll., Galway, Ireland). *Ir. J. Med. Sci.* 147(1):11-14; 1978.

Alterations of enzyme activities were investigated in intestinal biopsies from celiac and non-celiac subjects after 24 hr of maintenance in organ culture. Biopsies from 11 celiac patients and 10 non-celiac patients undergoing gastroenterological investigation were cultured for 24 hr at 37 C, then washed, wrapped in parafilm, and stored at -20 C along with washings and medium to await analysis. At 24 hr of culture, both celiac and non-celiac tissue showed morphological preservation of structure by dissecting microscope and histological examinations, although some areas of necrosis were observed. The protein content of the celiac mucosa decreased by 25-30% during culture ($p<0.02$). Statistically significant changes in enzyme activity were found as an increase in alkaline phosphatase activity (from 12.1 ± 9.5 to 20.1 ± 11.1 IU/

g protein, $p<0.02$) and a decrease in lactic de-
ydrogenase activity (from 323.9 ± 154.6 to 235.6 ±
12.7 IU/g protein) in the celiac mucosa. Activ-
ties of lactase, sucrase, leucyl β-naphthylamidase,
nd glucuronidase did not change significantly in
ither tissue.

946 FARMER'S LUNG DISEASE AND COELIAC DISEASE:
A PROSPECTIVE STUDY. (Eng.) Stevens, F.
.; Hitchcock, H. T. (Regional Hosp., Galway, Ire-
and). *Ir. J. Med. Sci.* 146(10):335-339; 1977.

o determine if the association noted between celiac
isease and diffuse pulmonary disease represents a
rue genetic relationship, a prospective study of
ine consecutive patients with farmer's lung disease
FLD) was carried out. All patients gave the typi-
al history of seasonal dyspnea and cough provoked
y exposure to moldy hay. Antibodies to *Micropoly-*
pora faeni were found in eight patients. Histo-
ompatibility locus antigen B8 was present in only
our patients. All small intestinal biopsies of
he FLD patients showed the presence of finger and
eaf villi, and none showed the convoluted or mo-
aic appearance characteristic of untreated celiac
isease. The alkaline phosphatase activity was
ignificantly higher in the FLD patients than in
ine controls ($p<0.05$). There was no significant
ifference in lactase activity or intraepithelial
ymphocytes between the patients and controls. The
esults of this preliminary investigation do not
upport the hypothesis of an association between
eliac disease and FLD.

947 PNEUMATOSIS CYSTOIDES INTESTINALIS AND
OBSTRUCTING INTUSSUSCEPTION IN CELIAC
ISEASE. (Eng.) Frank, P. H.; O'Connell, D. J.
Dept. Radiology, Univ. Chicago, 950 E. 59th St.,
hicago, IL 60637). *Gastrointest. Radiol.* 2(2):
09-111; 1977.

he case of a patient with celiac disease complica-
ed by pneumatosis cystoides intestinalis (PCI) of
he small intestine and obstructing intussusception
s presented. The patient, a 48-yr-old woman known
o have steroid-controlled celiac disease, pre-
ented with abdominal pain and distention. A chest
adiograph showed free air under the right diaphragm,
d a barium examination revealed a diffuse ab-
rmality consisting of nonpliable jejunal loops
th complete loss of the normal fold pattern and
ickening of the bowel wall. There was PCI in
everal ileal loops. The pneumoperitoneum was
ought to be secondary to the PCI. Five days later
e patient experienced acute abdominal pain; a
agnosis of an ileocolic intussusception was made
the basis of a plain abdominal radiograph and
nfirmed at laparotomy. Extensive pneumatosis
testinalis was found in the distal jejunum and
the distal 5 feet of the ileum, and the portion
the ileum containing the intramural gas was in-
lved in the intussusception. The authors believe
at the patient's documented celiac disease was
e cause of the small intestinal PCI. As polypoid
strointestinal lesions are well known for their
association with intussusception, the small intestinal gas cysts are thought to be the cause of the obstructing ileocolic intussusception.

6948 CELIAC DISEASE WITH JEJUNAL ULCERATION. (Eng.) Agrawal, R. M.; Benz, W.; Brodmerkel, G. J., Jr.; Cincala, R. P. (Allegheny General Hosp., 320 E. North Ave., Pittsburgh, PA 15212). *Am. J. Gastroenterol.* 68(3):300-303; 1977.

The case of a patient with jejunal ulceration complicating celiac disease is presented. The patient first experienced weight loss, periumbilical pain, nausea, and occasional vomiting at the age of 39. She remained essentially asymptomatic for the next 5 yr. When she again developed persistent crampy periumbilical pain, a review of an upper gastrointestinal series revealed small serrations in the duodenal walls in addition to some edematous changes in the mucosa. The lumen of the proximal jejunum appeared narrowed. These findings were confirmed by a repeat upper gastrointestinal series. Endoscopy showed esophagitis, diffuse gastritis, marked diffuse nodularity in the duodenum, and duodenitis. At this time, a biopsy showed flat mucosa with complete absence of villi. At surgery, one small ulcer was found in a resected segment of jejunum. The patient responded to a gluten-free diet, but died 18 months later; a lymph node biopsy had shown lymphosarcoma.

6949 SUCROSE MALABSORPTION IN MAN AFTER INGESTION OF α-GLUCOSIDE-HYDROLASE INHIBITOR. (Eng.) Caspary, W. F. (Dept. Medicine, Univ. Gottingen, W. Germany). *Lancet* 1(8076):1231-1233; 1978.

The effect of an α-glucosidehydrolase inhibitor (α-GHI) on intestinal sucrose absorption was assessed in seven healthy subjects by measuring rises in blood glucose and intestinal hydrogen production after the ingestion of 100 g sucrose. α-GHI (200 mg), given with the sucrose, completely inhibited early postprandial blood glucose rises, prevented late postprandial dips in blood glucose, and considerably increased breath hydrogen levels (the 30-min postprandial rise in blood glucose in each subject increased by over 30 ppm over baseline), which indicates sucrose malabsorption. Thus, the inhibitor can be used to study carbohydrate malabsorption and may be useful as a method for retarding carbohydrate absorption.

6950 DOUBLE BLIND STUDY OF MILK LACTOSE INTOLERANCE. (Eng.) Lisker, R.; Aguilar, L. (Istituto Nacional de la Nutricion, San Fernando y Viaducto, Tlalpan, Mexico 22). *Gastroenterology* 74(6):1283-1285; 1978.

A double-blind study was carried out in 150 subjects to determine the relationship between lactose malabsorption and milk lactose intolerance. Each participant received 250 ml of a different type of milk on three consecutive days. Milk A contained no lactose, milk B had 12.5 g, and milk C contained 37.5 g of lactose. After the experiment was completed, each subject was classified with a lactose tolerance test as having "sufficient" or "insufficient" lactase activity. Milk A produced no gastrointestinal symptoms in either sufficient or in insufficient persons. Milk B produced symptoms in 3.8% of sufficient and 37.1% of insufficient individuals, and milk C induced symptoms in 7.6% of sufficient and 83.5% of insufficient subjects. These differences are very highly significant ($p<0.0001$). It is concluded that lactose-intolerant subjects are indeed milk-intolerant and that the frequency with which symptoms occur in persons with lactose malabsorption increases in direct relation to the lactose content of the milk.

LARGE INTESTINE

6959 PROCTITIS AND ISCHEMIC COLITIS. (Fre.) De Witte, C.; Serste, J. P.; Dony, A. (Hopital de Schaerbeek, Boulevard Lambermont 220, 1030 Bruxelles, Belgium). *J. Belge Radiol.* 60(1): 113-116; 1977.

Two new cases of ischemic proctitis and colitis due to a vascular pathology (probably of the arterioles) near the inferior mesenteric artery are presented. The first patient (an 82-yr-old man) was admitted in cardiogenic shock with occlusive symptoms. Barium enema revealed typical lesions with "thumb print" marginal deformations of the upper descending colon. The lesions rapidly became diffuse and ulcerative, and the patient died on day 8 of a massive myocardial infarction. The second patient (an 89-yr-old woman) was seen for acute, massive rectal hemorrhage. Examination revealed ischemic lesions limited to the rectum, a rare location. The patient was treated with transfusions; the bleeding stopped and her condition improved. On day 30, rectoscopy showed a scarred, congested mucosa with a cicatricial stenosis at 10 cm of the anal margin. These ischemic lesions occur in old people or those with vascular deficiencies, although they have been reported in

women taking oral contraceptives. The radio-
ic image is characteristic: thickening of
al folds and the above thumb print deforma-
. A strict radiographic and endoscopic sur-
ance is always necessary, since the evolution
e lesions cannot be predicted by their orig-
appearance. Any increase in abdominal pain,
, or leukocytosis suggests an aggravation of
ondition and necessitates an exploratory lapa-
y.

SPONTANEOUS RESOLUTION OF COLONIC STRIC-
TURES CAUSED BY NECROTIZING ENTEROCOLITIS:
EUTIC IMPLICATIONS. (Eng.) Tonkin, I. L.
elland, J. C.; Hunter, T. B.; Capp, M. P.;
H.; Ermocilla, R. (Univ. Arizona Health Sci-
Center, Tucson, AZ 85724). *Am. J. Roentgenol.*
:1077-1081; 1978.

inical course of seven infants with colonic
ures after surviving necrotizing enterocoli-
described. Only two demonstrated the find-
fixed fibrotic stricture described in the
ture, while the remaining five showed atypical
raphic and pathologic features. Two of the
howed partial or spontaneous resolution of
crotizing enterocolitis colonic stenoses
low-up barium enema studies. In three of four
ts with colonic resections, the histopatho-
examination revealed a surprising absence of
rsible fibrosis or cicatrix formation. Cur-
urgical practice dictates elective resection
se narrowed colonic segments. The radiologic
thologic findings in this series of patients
t that surgical resection may be unnecessary
ected cases.

GIANT SIGMOID DIVERTICULUM: CLINICAL AND
RADIOLOGICAL FEATURES. (Eng.) Foster, D.
ss, B. (Royal Hosp., Sheffield, England).
(12):1051-1053; 1977.

se reports of giant sigmoid diverticulum as-
ed with diverticular disease of the sigmoid
are presented. The patients, a 61-yr-old
and an 86-yr-old man, presented with abdominal
f several weeks' duration, and the man had
bleeding. Abdominal films in the first pa-
showed a large gas-filled cyst occupying the
r part of the abdomen and containing a fluid
The lesion measured 29 cm in diameter. At
tomy, the cyst was found to be adherent an-
ly to the uterus and bladder. Barium meal
ation in the second patient showed a large
lled structure lying in the epigastrium and
cing the stomach. A barium enema examina-
owed diverticular disease of the sigmoid
with a large solitary diverticulum arising
ts superior margin. A defunctioning colos-
s carried out in the first patient and a
l colectomy with an end-to-end anastomosis
second. Pathological examination of the
ed specimens revealed communication with the
l colon in the second patient but not in the
The radiological finding of a large lucent
cystic structure related to the sigmoid colon in an elderly patient is suggestive of a giant sigmoid diverticulum. This suggestion was confirmed by barium enema examination, and the treatment of choice is surgical removal.

6962 IS THERE A MYOELECTRICAL ABNORMALITY IN THE IRRITABLE COLON SYNDROME? (Eng.)
Taylor, I.; Darby, C.; Hammond, P.; Basu, P. (Dept. Surgery, Univ. Liverpool, Liverpool, England). *Gut* 19(5):391-395; 1978.

The colonic myoelectrical pattern of 10 patients with the irritable colon syndrome and who had an abnormality of the 0.05 Hz [3 cycles/min (c/m)] slow wave electrical activity of the distal colon was compared with that in 10 patients with assorted disorders with similar symptoms (e.g., chronic pancreatitis, diverticular disease, and ulcerative colitis) to determine whether this abnormality is related to small bowel habit alone or whether it is specific to the irritable colon syndrome. Transit time, stool weights, percentage motility, and slow wave electrical activity were measured in each patient. The two groups were matched for age, and patients with similar symptoms in the two groups had similar values for transit time and percentage motility. There was a statistically significant increase in the 3 c/m electrical activity in patients with the irritable colon syndrome unrelated to the degree of diarrhea or constipation (43.9 ± 15.8% in patients with constipation and 51.1 ± 4.7% in patients with diarrhea in the irritable colon group, versus 13.2 ± 6.8% and 9.2 ± 3.7%, resp., in the patients without irritable colon). It appears that the abnormally high incidence of 3 c/m electrical activity in the colon is specific to the irritable colon syndrome and not merely a feature of altered bowel habit.

6963 INTESTINAL POLYPOSIS: A GENETIC DISEASE. (Fre.) Plauchu, H.; Bigay, D.; Casteu, J. G.; Guillemin, G.; Robert, J. M. (Service de Genetique, Hotel Dieu, F 69288 Lyon Cedex 1, France). *Lyon Med.* 239(1):21-30; 1978.

A study of 32 patients with intestinal polyposis and their 22 families confirmed that the disease is transmitted by an autosomal dominant gene with incomplete penetrance and variable expressivity. A detailed study of eight families, including complete family histories and barium enemas of all the family members, demonstrates the wide variability in the onset and course of the disease. Some family members showed symptoms at age 2, while others remained healthy until 60 yr; there is a similar wide age range at which the polyps became cancerous (age 20-65). The association of Gardner's syndrome (osteomas and epidermoid tumors) and Turcot's syndrome (nervous tissue tumors) with rectocolic polyposis in one family suggests the identical genetic transmission of all three diseases. The authors stress the need of regular checkups (especially double-contrast barium enemas) for all family members of patients with familial rectocolic polyposis. Any relatives found to have polyposis should immediately undergo a prophylactic colectomy. The conservation of the rectum will depend on whether all rectal polyps can be removed, the willingness of the patient to submit to life-long surveillance, removal of new polyps, and, of course, the presence of degenerated polpys in the rectum itself. Tracking down and examining all family members for intestinal polyposis is recommended.

6964 CARCINOMA IN SITU OF THE DISTAL PART OF THE COLON AND OF THE RECTUM. (Eng.) Rittenhouse, M. C.; Copeland, E. M., III. (M. D. Anderson Hosp. Tumor Inst., Houston, TX). *Surg. Gynecol. Obstet.* 146(2):225-229; 1978.

The cases of 103 patients with carcinoma *in situ* of the rectum, rectosigmoid, and sigmoid colon diagnosed between 1944 and 1974 were evaluated retrospectively. In 42 patients, carcinoma *in situ* was unassociated with other malignant disease or medical illness; 43 had synchronous invasive carcinoma of the colon; 7 had a history of invasive carcinoma of the colon; and 9 had an associated cancer not involving the colon. The majority of lesions occurred within an adenomatous polyp. Among the 42 patients with carcinoma *in situ* alone, one-third were asymptomatic, 18 had bleeding, and 5 each had a change in intestinal habits or abdominal pain. The diagnosis was made by sigmoidoscopy in 34 patients, by operation in 7, and by colonoscopy in 1. Adequate excision, either locally or by colonic resection, was all that was required in these patients; however, two developed metachronus carcinoma of the colon and one later had a solitary metastasis to the liver, indicating that these patients should be observed indefinitely by frequent barium enemas and sigmoidoscopy. Of the 43 patients with carcinoma *in situ* and synchronous invasive colon carcinoma, only 12% were asymptomatic, and 38% had more than one symptom. Carcinoma *in situ* was diagnosed either by sigmoidoscopic biopsy (58%) or by examination of the resected surgical specimen (42%). Prognosis and treatment were determined by the nature of the invasive lesion, and colonic resection was performed in 85% of these patients. At the most recent follow-up, 11 were alive without evidence of disease, 1 was alive with metastasis, 11 were dead of other causes, and 20 were dead of metastatic carcinoma of the colon (only 3 of these survived for ≥5 yr after treatment). Of the seven patients with a history of carcinoma, the time elapsing between treatment of the prior carcinoma and the diagnosis of carcinoma *in situ* was <3 yr in four patients and <10 yr in all patients. All seven survived at least 5 yr and two developed a third carcinoma of the colon. In the nine patients with other carcinomas (lung in 3; breast, nasopharynx, cervix, and kidney in 1 each; stomach in 2), the invasive malignant disease determined the prognosis, and all were dead within 5 yr of the diagnosis of carcinoma *in situ* of the colon.

LARGE INTESTINE

Ulcerative Colitis

7017 MENTAL DISORDERS IN ULCERATIVE COLITIS: SUICIDE, DIVORCE, PSYCHOSIS, HOSPITALIZATION FOR MENTAL DISEASE, ALCOHOLISM, AND CONSUMPTION OF PSYCHOTROPIC DRUGS IN 178 PATIENTS SUBJECTED TO COLECTOMY. (Eng.) Gruner, O. P. N.; Naas, R.; Gjone, E.; Flatmark, A.; Fretheim, B. (Rikshospitalet, Oslo 1, Norway). *Dis. Colon Rectum* 21(1):37-39; 1978.

The incidence of mental disorders, divorce, alcoholism, and consumption of psychotropic drugs in 178 patients who underwent colectomy for the treatment of ulcerative colitis was compared with that in the general Norwegian population. The frequencies of suicide, divorce, psychosis, hospitalization for mental disorders, and consumption of psychotropic drugs did not differ significantly from corresponding frequencies in the general population.

7018 CLINICAL OUTCOME OF THE FIRST TEN YEARS OF ULCERATIVE COLITIS AND PROCTITIS. (Eng.) Ritchie, J. K.; Powell-Tuck, J.; Lennard-Jones, J. E. (St. Mark's Hosp., City Rd., London EC1V 2PS, England). *Lancet* 1(8074):1140-1143; 1978.

Two hundred sixty-nine patients with ulcerative colitis and a history of less than 6 months when first seen at St. Mark's Hospital in the decade 1966-75 were followed for up to 11 yr in a study of the mortality and prognosis of this disease. The outcome was correlated with the maximum extent of the disease observed within 3 months of presentation. Seventy-five patients required hospital admission, 56 within 1 yr of presentation. Extensive colitis developed in 60 patients. The cumulative probability of the disease being extensive was 21 ± 3% at 5 yr and 29 ± 4% at 10 yr. Twenty-five patients required surgical treatment. The cumulative probability of operation was 8 ± 2% at 5 yr and 15 ± 4% at 10 yr. Nineteen patients are known to have died. The expected number of deaths was 19.2.

7019 STROKES AND ULCERATIVE COLITIS. (Eng.) Mayeux, R.; Fahn, S. (Presbyterian Hosp., New York, NY). *Neurology* 28(6):571-574; 1978.

The cases of three young patients who had ulcerative colitis and cerebral thrombosis are presented. The first two patients, a 12-yr-old boy and a 17-yr-old girl, experienced more than one episode of thromboembolic disease. The boy first developed left focal motor seizures during treatment for an exacerbation of colitis. The seizures were controlled with anticonvulsants, but a dense left hemiparesis persisted. This condition slowly improved, but he had two subsequent episodes of thrombophlebitis of the right leg. The girl developed a sudden loss of vision in the left eye during treatment for an exacerbation of colitis. The optic disk was pale, and there were small hemorrhages in the periphery, compatible with central retinal artery occlusion. She developed left focal motor seizures, left homonymous hemianopia, and left hemiparesis. Except for nonspecific arthralgia and atopic eczema in this patient, neither of the patients had evidence of any other extracolonic manifestation of ulcerative colitis. Clinical and laboratory data indicated arterial occlusion in these two cases. The third case was a 26-yr-old woman who developed right focal motor seizures 50 hr after undergoing a total proctocolectomy. Following the seizures, there was fluent aphasia and right hemiparesis. All patients survived, and the neurologic symptoms gradually improved. Systemic arterial and venous thromboembolic complications occur often in ulcerative colitis, but stroke is uncommon. Abnormalities in the early stages of clotting may be responsible, and the risk of thromboembolic phenomena in young patients seems to increase with exacerbations of this form of chronic inflammatory bowel disease.

PANCREAS

7029 EFFECT OF SALIVA FROM CYSTIC FIBROSIS PATIENTS AND FROM NORMAL SUBJECTS ON RED BLOOD CELL SODIUM TRANSPORT. (Eng.) Grinwald, P. M.; Segal, M. B. (St. Thomas' Hosp. Medical Sch., Lambeth Palace Rd., London, SE1 7EH, England). *Pediatr. Res.* 12(1):1-3; 1978.

To determine whether saliva contains substances that may be relevant to the transport abnormality in cystic fibrosis, the effect of saliva from cystic fibrosis patients on RBC sodium transport was compared with that from normal subjects. RBC from cystic fibrosis patients exhibited a significantly decreased ($p<0.01$) ouabain-insensitive fraction of Na^+ efflux compared with normal controls. Saliva taken from both the patients and the normal subjects caused an increase in Na^+ efflux from normal RBC, either in presence or absence of ouabain (0.1 mM), of 19% to 29% as compared with untreated control RBC. There was no significant difference between the effects of cystic fibrosis saliva and normal saliva. The model in this study has not confirmed that a modification of the cell membrane by uncharacterized circulating or secreted factors may be involved in the transport abnormality in cystic fibrosis.

7030 PANCREATIC PSEUDOCYSTS: UNUSUAL ULTRASOUND FEATURES. (Eng.) Conrad, M. R.; Landay, M. J.; Khoury, M. (Parkland Memorial Hosp., 5201 Harry Hines Blvd., Dallas, TX 75235). *Am. J. Roentgenol.* 130(2):265-268; 1978.

Three cases of pancreatic pseudocyst having unusual findings on the sonogram are presented. All patients were alcoholics. In one patient, the renal parenchyma was markedly compressed between the anterior and posterior components of the perinephric pseudocyst so that an intrinsic renal mass was mimicked on the excretory urogram. The correct diagnosis was made by the determination of the amylase in the aspirated fluid. In the second case, sonography revealed a large cystic mass in the left upper quadrant contiguous with and displacing the spleen medially. The lateral location of the cystic mass and the lack of a continuous distinct interface between the cystic mass and the spleen resulted in confusion with a splenic subcapsular hematoma. The large necrotic pseudocyst was discovered at surgery. The phlegmenous inflammatory reaction associated with it probably was responsible for obscuring the interface between the pseudocyst and the spleen. In the third patient, the sonographic findings were indistinguishable from those seen in a perinephric abscess. However, the patient's good renal function and a well-defined renal margin on the excretory urogram suggested that this diagnosis was unlikely. The elevated amylase in the purulent aspirated fluid established a definitive diagnosis of an infected dissecting pseudocyst, of which only the small posterior perinephric portion was appreciated on the sonogram. Pancreatic pseudocysts must be considered in all patients with a history of chronic alcoholism who have evidence of an abnormal cystic collection by sonography.

PANCREAS

Pancreatitis

7038 ELEVATED SERUM ALKALINE PHOSPHATASE LEVEL MAY AID IN THE DIAGNOSIS OF PANCREATITIS. (Eng.) Hislop, I. G.; Ryan, G. P. (Fremantle Hosp., Adelaide, Australia). *Med. J. Aust.* 2(7):209-211; 1977.

The occurrence of an elevated serum alkaline phosphatase (SAP) level in some patients with pancreatitis was studied in 10 patients. Seven patients had alcoholic pancreatitis, whereas the remaining three drank little or no alcohol. The SAP levels were intermittently and variably raised. There was usually a close relationship between pain and a rise in the SAP levels, but other laboratory investigations often failed to support a diagnosis of pancreatitis, the serum and urinary amylase levels being normal or minimally raised. However, when the SAP level exceeded twice normal values, serum or urinary amylase values generally indicated a clinical diagnosis of pancreatitis. To exclude coexisting hepatic disease, liver function was assessed in all cases. The bilirubin levels were normal in all cases, and the aspartate transaminase levels were only mildly elevated in two patients (148 U and 111 U, resp.). SAP estimation may assist in establishing a clinical diagnosis in cases of abdominal pain in which pancreatitis is suspected.

7039 THE CEA CONCENTRATION IN DUODENAL FLUID IN PATIENTS WITH PANCREATIC DISEASE.

(Eng.) Rolny, P.; Elwing, H.; Nilsson, L. A. (Dept. Surgery III, Univ. Goteborg, Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(6):759-763; 1977.

Six patients with pancreatic carcinoma, 10 patients with chronic alcoholic pancreatitis, 10 patients with other upper abdominal nonpancreatic diseases, and 10 healthy volunteers were studied to establish whether carcinoembryonic antigen (CEA) determination in duodenal fluid obtained during the secretin-cholecystokinin (CCK) test can give additional information for the diagnosis of pancreatic disease and for differentiation between inflammatory and malignant pancreatic disease. The CEA concentration in the duodenal fluid after secretin-CCK stimulation in healthy volunteers ranged from 2.5 ng/ml to 25 ng/ml. Four of the patients with pancreatic carcinoma had a concentration that was equal to or exceeded 25 ng/ml, and three had concentrations greater than 50 ng/ml. The levels were higher than 25 ng/ml in all 10 patients with chronic pancreatitis, and the level was over 50 ng/ml in 6 of them. All but one of these patients had abnormal pancreatic secretion. A CEA concentration greater than 50 ng/ml occurred in 3 of the 10 patients with other abdominal diseases. It is concluded that a high CEA concentration in duodenal fluid after secretin-CCK stimulation does not necessarily indicate pancreatic carcinoma. The level may also be elevated in nonpancreatic diseases.

7040 ACUTE PANCREATITIS FOLLOWING RENAL ALLOTRANSPLANTATION: A LETHAL COMPLICATION.

(Eng.) Taft, P. M.; Jones, A. C.; Collins, G. M.; Halasz, N. A. (Univ. California Medical Center, San Diego, 225 W. Dickinson St., San Diego, CA 92103). *Am. J. Dig. Dis.* 23(6):541-544; 1978.

The cases of six patients who developed acute pancreatitis following renal allotransplantation are presented. The first patient, a 29-yr-old man, was thought to have developed pancreatitis as a result of the immunosuppressive regimen, which included azathioprine (75 mg, q.i.d.). He has had no relapse after this drug was stopped. He did have a history of recurrent abdominal pain since the age of 16, but there was no proof that it was related in any way to his subsequent pancreatitis. In the second patient, a strong alcoholic history, the immunosuppressive drugs, and a penetrating posterior peptic ulcer could have been involved in the development of fatal pancreatitis. Pancreatitis in the third patient was related to secondary or tertiary hyperparathyroidism. Cessation of immunosuppressive therapy and the intentional sacrifice of the renal graft in an attempt to reverse the progressive sepsis in this patient failed, resulting in his death. In the fourth patient, the insidious nature of post-transplantation pancreatitis was well illustrated. There was no prodrome and no suggestive symptomatology, until the patient presented with a full-blown surgical abdomen. The patient was found to have cholelithiasis, but since the pancreatitis involved only the distal pancreas, it was doubtful that this condition was etiologic. The patient died after he developed a high jejunal fistula with continuing sepsis and progressive pulmonary insufficiency. The fifth patient developed pancreatitis during the second week of treatment for allograft rejection. His initial presentation for rejection may have actually been the early stage of pancreatitis. His alcohol abuse may have set the stage of susceptibility to other agents, such as his immunosuppression, which resulted in clinical pancreatitis. The last patient presented with progressive adult respiratory distress syndrome for which no etiologic agent could be identified. At autopsy, he was found to have acute pancreatitis and no primary pulmonary infection as the cause of death.

7041 CHOLEDOCHOCELE DEMONSTRATED ON PERCUTANEOUS CHOLANGIOGRAPHY: A PATIENT WITH ACUTE FULMINANT PANCREATITIS.

(Eng.) Jones, B. (Harvard Medical Sch., 25 Shattuck St., Boston, MA 02115). *Gastrointest. Radiol.* 2(2):145-147; 1977.

The case of a patient in whom a choledochocele, demonstrated by percutaneous cholangiography, was associated with the development of acute fulminant pancreatitis is presented. The patient, a 37-yr-old woman, had previously undergone a bilateral nephrectomy for progressive renal failure due to scleroderma. She developed severe upper abdominal pain that remained unexplained for 4 yr after her initial presentation. A number of gastrointestinal series and an oral cholecystogram had been negative. At the last hospital admission, acute pancreatitis was the clinical diagnosis. This condition apparently deteriorated into hemorrhagic pancreatitis, almost certainly aggravated by her anticoagulant therapy, which she had received since the time of the nephrectomy. The anticoagulant therapy was stopped, and cholangiography was performed. The well-developed class III choledochocele was demonstrated by this procedure. It was decided to postpone surgery until her condition had stabilized, but despite improving liver function tests and decreasing amylase, the patient died 1 week after the diagnosis was made. The altered pressure dynamics and compromised drainage of the biliary and pancreatic ducts by their insertion into the choledochocele was the probable mechanism for the development of obstructive jaundice and acute pancreatitis. Because this rare lesion is potentially curable with surgery, its identification by percutaneous or i.v. cholangiography has important clinical significance.

)42 A SINGLE-CENTRE DOUBLE-BLIND TRIAL OF TRASYLOL THERAPY IN PRIMARY ACUTE PANCREA-

ITIS. (Eng.) Imrie, C. W.; Benjamin, I. S.;
erguson, J. C.; McKay, A. J.; Mackenzie, I.; O'Neill,
.; Blumgart, L. H. (Royal Infirmary, Glasgow, Scot-
and). *Br. J. Surg.* 65(5):337-341; 1978.

double-blind trial of i.v. aprotinin (Trasylol)
erapy as a supplement to a standard regimen of
nservative management was carried out in 161 pa-
ents with primary acute pancreatitis. The pa-
ents were subdivided into younger (<60 yr) and
der patients (≥60 yr), and subjects in each group
re randomly allocated either to Trasylol therapy
tarter 500,000 KIU and thereafter 200,000 q.i.d.
r 5 days) or to placebo. There were 14 deaths
.7%), 7 in the Trasylol and 7 in the pla-
bo group, and no significant difference was found
either the mortality or the major complications
te, either overall or within either age group.
l 14 patients who died met the objective criteria
r severe acute pancreatitis determined by the
esence of at least three of a possible nine fac-
rs during the first 48 hr of admission. Severe
ute pancreatitis was present in 37% of patients,
o were evenly distributed between the Trasylol and
acebo groups. Neither in those patients with
vere nor in those with less severe acute pancre-
itis was there any significant difference between
e two therapeutic regimens. Supplementary Trasylol
erapy at this dosage confers no advantage over
andard conservative treatment in the management
patients with primary acute pancreatitis.

43 SPECIFICITY OF INCREASED AMYLASE TO CREATININE CLEARANCE RATIO IN ACUTE PANCREATI-

S. (Eng.) Lankisch, P. G.; Koop, H.; Otto, J.;
erdieck, U.; Winckler, K.; Wolfrum, D. I. (Medi-
nische Universitats Klinik, Humboldtallee 1,
3400 Gottingen, W. Germany). *Digestion* 16(1/2):
0-164; 1977.

udies were carried out in 33 patients with acute
ncreatitis to determine whether the amylase to
eatinine clearance ratio (C_{am}/C_{cr}) is specific
r acute pancreatitis and whether this index is
re useful than routine estimation of serum and
ine amylase in these cases. It has been suggested
at a ratio above 5.3% is specific for acute pan-
eatitis. Twenty-one healthy persons and 19 pa-
ents with renal insufficiency served as controls.
the 21 normal controls, the mean C_{am}/C_{cr} ratio
s 1.8 ± 1.0%. On the day of admission, 28/33
tients with acute pancreatitis had elevated serum
d/or urinary amylase levels; however, the C_{am}/C_{cr}
tio was below 5.3% in 10/28 and raised in 18/28 pa-
ents. In the remaining five patients with acute
ncreatitis, the amylase level was not elevated at
e first estimation of the ratio; in one, the ratio
s below 5.3% and remained so when amylase increased
e following day and in the remaining four, the ra-
o was raised. In 19 patients with renal insuffici-
cy (serum creatinine >1.5 mg%), the ratio was above
3%. Follow-up examinations showed that the estima-
ons of the C_{am}/C_{cr} ratio and serum amylase in one
tient with acute pancreatitis was only twice elevated above normal during the course of the disease and, as in the other cases studied, did not seem to parallel the amylase level. The results suggest that the C_{am}/C_{cr} ratio is not a specific index in the diagnosis of acute pancreatitis.

7044 PANCREATIC AND SALIVARY AMYLASE/CREATININE CLEARANCE RATIOS IN NORMAL SUBJECTS AND IN PATIENTS WITH CHRONIC PANCREATITIS.

(Eng.) Hegarty, J. E.; O'Donnell, M. D.; McGeeney, K. F.; Fitzgerald, O. (Royal Postgraduate Medical Sch., Hammersmith Hosp., London, England). *Gut* 19(5): 350-354; 1978.

The clearance of pancreatic and salivary amylase relative to creatinine was measured in 26 control subjects and 22 patients with chronic pancreatitis to ascertain the value of the amylase/creatinine clearance ratio in the diagnosis of this disease. Control values for pancreatic amylase clearance were 2.64 ± 0.86% compared with 1.54 ± 0.95% for salivary amylase. In chronic pancreatitis, pancreatic amylase clearance ratios were significantly higher than controls ($p<0.0005$, mean 4.09 ± 1.63). The difference in clearance rate of salivary amylase did not reach a level of significance when compared with the control group. Twelve of the 22 patients showed pancreatic amylase clearance values above the normal limit of 4.4, while only 5 were abnormal when the clearance of total amylase was measured. The patients also showed statistically higher ($p<0.0005$) levels of serum salivary amylase when compared with 69 control sera. No such difference was found for the pancreatic component of serum amylase. Comparison of β_2-microglobulin clearance values showed no statistical difference between patients and controls. The results suggest that this rapid, simple, reproducible, and inexpensive method should be included as part of the investigation of patients with suspected chronic pancreatitis.

7045 VISCOSITY AND TRYPSIN ACTIVITY OF PURE PANCREATIC JUICE IN CHRONIC PANCREATITIS.

(Eng.) Tympner, F.; Rosch, W. (Tympner, Medizinische Klinik mit Poliklinik der Universitat Erlangen-Nurnberg, Krankenhausstr. 12, 8520 Erlangen, W. Germany). *Acta Hepatogastroenterol.* 25(1):73-76; 1978.

The viscosity and trypsin activities of pure pancreatic juice were determined in 20 patients with chronic pancreatitis and compared with those in 20 healthy subjects. Both trypsin activity and viscosity were significantly greater in the patients with pancreatitis than in the healthy subjects ($p<0.01$). The determination of viscosity and trypsin activity in pure pancreatic secretions may be useful in the diagnosis of chronic pancreatitis.

LIVER AND BILIARY TRACT

7067 DIAGNOSTIC SIGNIFICANCE AND SPECIFICITY OF BILE CANALICULI ANTIBODY (BCA) IN PATIENTS WITH DIFFERENT LIVER DISEASES AND IN NORMAL CONTROLS. (Ger.) Hess, G.; Arnold, W.; Meyer zum Buschenfelde, K. H. (II. Medizinische Universitatsklinik und Poliklinik, Langenbeckstrasse 1, 6500 Mainz, W. Germany). *Innere Med.* 3(3):131-136; 1976.

Sera from patients with various hepatopathies and from healthy control subjects were tested for the presence of bile canaliculi antibodies (BCA) by the fluorescent antibody technique using cryostat sections of bovine liver. The incidences of BCA were 21/45 in acute hepatitis, 34/65 in chronic active hepatitis (24/29 in hepatitis B surface antigen [HBsAg]-negative and 10/16 in HBsAg-positive patients), 6/24 in liver cirrhosis, 4/17 in primary biliary cirrhosis, 14/39 in clinically healthy HBsAg carriers, and 7/48 in control subjects. It was not possible to clarify the antigenic substrate. In agreement with data in the literature, these results show that the occurrence of BCA has no substantial diagnostic or prognostic value.

7068 ASSESSMENT OF FAT CONTENT OF LIVER BY A PHOTON SCATTERING TECHNIQUE. (Eng.) Puumalainen, P.; Olkkonen, H.; Sikanen, P. (Dept. Physics, Univ. Kuopio, SF-70101 Kuopio 10, Finland). *Int. J. Appl. Radiat. Isot.* 28(9):785-787; 1977.

A photon-scattering method was applied to the measurement of the fat content of the liver in autopsy specimens from five normal subjects and from nine patients with diffuse liver diseases. This technique is based on the determination of the coherently- and Compton-scattered photons in a narrowly collimated geometry using a semiconductor detector and a multichannel analyzer. In the energy spectrum, the peaks due to coherently- and Compton-scattered photons are well distinguished. The ratio of the peak areas comes from $A_{coh}/A_{Compt}=\overline{Z}^3\overline{A}/\overline{Z}$ where $\overline{Z}$ and $\overline{A}$ are the average atomic and mass numbers of the target atoms. The three fatty liver specimens and the four with stasis had significantly lower coherent/Compton ratios compared with normal specimens ($p<0.01$). The coefficient of variation of the repeated studies was under 2%. Equipment suitable for *in vivo* measurement of liver fat content is presented. A broadly collimated 500 mCi ^{241}Am annular source was used as a radiation source and a Ge semiconductor crystal as a detector. A rectangular liver phantom immersed into a water tank was used to test the validity of the method. The phantom was filled with varying concentrations of *tert*-butanol, whose effective charge number is close to that of fatty tissue. The A_{coh}/A_{Compt} ratio correlated highly significantly with the *tert*-butanol content ($r=0.997$). The coefficient of variation was under 3%. This method seems feasible for liver fat measurements *in vivo*, e.g., in following the progress of a disease or the effect of a treatment.

7069 RELATIONSHIP BETWEEN LIVER TESTS AND SERUM IgA, IgM and IgG LEVELS. (Pol.) Hankiewicz, J.; Bujniewicz, E. (I Klinika Chorob Wewnetrznech, Instytut Chorob Wewnetrzynch Sl. AM, ul. Podchorazych 3 m 13, 40-043 Katowice, Poland). *Przegl. Lek.* 35(3):337-342; 1978.

Correlations were studied between the serum IgA, IgG, and IgM levels and the results of liver tests (thymol, Takata-Ara, cadmium, iodide, Kunkel, 66-test, and uranyl acetate test) in 43 patients with liver diseases, 8 patients with diseases of the bile ducts, 20 patients with other diseases, and 12 healthy controls. Correlation was found between the serum immunoglobulin levels and the test results: the increases in the test parameters were usually accompanied by increases in the immunoglobulin levels; however, not all results of all tests changed in this manner. The negative liver tests were usually accompanied by a lack of change of the immunoglobulin levels. Increases in measured parameters were accompanied mainly by increased IgG levels. Positive Takata-Ara, iodide, cadmium, and Kunkel tests, with a simultaneous lack of change in the thymol test and 66-test, were usually accompanied by an increased IgA level. Changes in the thymol and 66-tests were reflected principally by changes in the IgM levels.

7070 DIAGNOSTIC APPLICABILITY OF INTRA-VITAL MORPHOLOGIC EXAMINATION OF THE LIVER IN CHRONIC HEPATOPATHY. (Pol.) Nowak, H. F.; Boron, P.; Dadan, H.; Szpakowicz, T.; Zalewski, J. (Klinika Chorob Zakaznych, 15-540 Bialystok, Poland). *Patol. Pol.* 28(4):515-519; 1977.

The diagnostic value of intravital morphological investigation of liver specimens obtained by biopsy or by curative or exploratory surgery in 71 patients with various hepatopathies was studied and compared with the clinical diagnosis. The histomorphological diagnosis was in agreement with the clinical diagnosis in 43/71 cases (in 8/15 patients with chronic persistent hepatitis, in 5/9 patients with chronic aggressive hepatitis, in 1/7 patients with chronic aggressive hepatitis with cirrhosis, in 1/2 patients with liver cirrhosis, in 1/8 patients with unspecific chronic hepatitis, in 1/3 patients with primary liver carcinoma, and in 26/27 patients with hepatic metastases). Among the 28 cases in which the histomorphological diagnosis did not agree with the clinical one, exacerbated chronic cholecystitis was diagnosed clinically in 13 cases, liver cirrhosis in 11, and status after viral hepatitis in 2. No clinical diagnosis was established in one case. The findings indicate the usefulness of intravital morphological examination of the liver in conjunction with other diagnostic methods for defining accurately the type of diffuse hepatic lesions and the type of liver tumors involved.

7071 DIAGNOSIS OF EXTRA-HEPATIC ABNORMALITIES ON DYNAMIC STUDY OVER THORACO-ABDOMINAL REGION PRIOR TO HEPATIC IMAGING. (Eng.) Siddiqui, A. R.; Wellman, H. N. (Indiana Univ. Sch. Medicine, 1100 W. Michigan, Indianapolis, IN 46202). *Clin. Nucl. Med.* 3(6):214-216; 1978.

Findings in 262 thoraco-abdominal dynamic studies done at the time of hepatic imaging are reviewed to determine the number and types of extrahepatic abnormalities. Twenty-nine extrahepatic abnormalities were diagnosed solely on the basis of these studies, including pericardial and pleural effusions and decreased perfusion to one lung. Half of these abnormalities were not suspected clinically. The dynamic study is an important part of hepatic imaging and should be performed routinely. Besides aiding in the differential diagnosis of various hepatic lesions, extrahepatic abnormalities can be discovered.

7072 PERCUTANEOUS TRANSHEPATIC CHOLANGIOGRAPHY WITH THE CHIBA NEEDLE. (Por.) Onishi, I.; Carrilho, F. J.; Paranagua, D. F.; Zeitune, J. M. R.; Muarrek, F. J.; Pareja, J. C.; *et al.* (Setor de Radiologia da Gastroclinica de Londrina, Universidade Estadual de Londrina, Londrina, Brazil). *Arq. Gastroenterol.* 14(4):205-209; 1977.

Percutaneous transhepatic cholangiography (PTC) with the Chiba needle was performed in 50 patients with intrahepatic or extrahepatic cholestasis. A success rate of 88% was achieved whether or not the intrahepatic bile duct was dilated. Neoplasia of the bile ducts, head of the pancreas, papilla, and gallbladder were diagnosed in 18 cases, cholelithiasis in 15, acute hepatitis in 3, chronic cholangitis in 2, chronic cholangitis in 2, cholecystoduodenal fistula in 1, pseudocyst of the head of the pancreas in 1, iatrogenic stenosis of the common bile duct in 1, inflammation of the papilla in 1, and pathology of unknown origin in 2. The success rate was 18/18 for neoplasias; 16/18 for cholelithiasis; 6/9 for hepatitis and cholangitis, 3/3 for fistulas, pseudocysts, and iatrogenic stenosis; and 1/2 for pathology of unknown origin. PTC was well tolerated; hemorrhage occurred in only one patient. The findings indicate the great value of PTC in the diagnosis of cholestasis.

7073 PORTAL DIVERSION FOR HEPATIC METABOLIC DISEASES. (Fre.) Bismuth, H.; Franco, D.; Grange, D. (Hopital Paul-Brousse, F 94800 Villejuif, France). *Gastroenterol. Clin. Biol.* 1(11):903-916; 1977.

A review of the use of portal diversions for the management of liver glycogenosis and hypercholesterolemia is presented. Terminolateral (19) and laterolateral (1) portacaval anastomoses and portacaval transpositions (3) were performed to correct severe glycogenosis (types I, III, and VI) involving life-threatening hypoglycemic accidents, very frequent meals, and growth and/or psychomotor retardation. Complete or partial correction of the hypoglycemia and improved tolerance to fasting occurred in all patients; lactic acidosis, hyperuricemia, and platelet disorders usually disappeared entirely, and remarkable growth spurts were seen in most cases. Improvement was often very gradual and sometimes took up to 1 yr. No specific complications arising from the portal shunt (specifically, no encephalopathies) were seen in any patients up to 10 yr after surgery. Familia type II hyperlipoproteinemia, an autosomal dominant disorder, in its homozygous form generally leads to death before age 20 from atherosclerotic complications. Terminolateral anastomoses have been performed on 11 patients with this disease. All patients benefited from an improvement in symptoms, including the disappearance of xanthomas and an average decrease of 40% in plasma cholesterol and beta-lipoproteins. Angina lessened in five of eigh patients, allowing an increase in physical activity Although atheromatous lesions did not regress, thei evolution was arrested. Even though long-term resu are not yet available on these patients, the surgery is recommended for homozygous patients showing early xanthomas whose serum cholesterol and betalipoproteins cannot be reduced by at least 40% through medical treatment. The mechanism by which portal shunts ameliorate these metabolic disorders is not fully known, although it probably involves the increased availability of peripheral glucose and/or insulin in glycogenosis and a diminished synthesis or accelerated degradation of cholesterol in hypercholesterolemia.

7074 UPTAKE OF IRON BY DUODENAL BIOPSY SPECIMENS FROM PATIENTS WITH IRON-DEFICIENCY ANAEMIA AND PRIMARY HAEMOCHROMATOSIS. (Eng.) Cox, T. M.; Peters, T. J. (Royal Postgraduate Medical Sch., Du Cane Rd., London W12 OHS, England). *Lancet* 1(8056):123-124; 1978.

To investigate the control of iron absorption, initial rates of iron uptake by duodenal mucosa were determined in biopsy specimens from 12 normal subjects, 4 patients with iron deficiency anemia, and 5 patients with primary hemochromatosis. The mucosal iron content in patients with iron deficiency anemia was significantly lower than that in controls ($p<0.05$). When the Fe^{3+} concentration of the incubation medium was 450 μM, there was a threefold increase in iron uptake by biopsy specimens from patients with iron deficiency anemia ($p<0.01$). Uptake at 180 μM Fe^{3+} was also increased. At the higher concentration of 450 μM, iron uptake by specimens from patients with hemochromatosis was no different from normal. In controls and patients with hemochromatosis, unidirectional iron uptake reached a saturation point over the concentration range 18-450 μM Fe^{3+} in the incubation medium. Although uptake at the higher iron concentrations was similar in the two groups, at the lower concentrations, uptake in hemochromatosis patients was significantly greater. Kinetic analysis showed a significantly lower apparent K_t for iron uptake by the mucosa from patients with hemochromatosis (34 ± 6 μM) compared with controls (125 ± 54 μM, $p<0.05$), although the V_{max} was not different. In iron deficiency, there was a significant increase in V_{max} (27.2 ± 7.1 pmol/mg/min) in comparison with controls (9.3 ± 1.5, $p<0.01$), and there was an associated rise in K_t (290 ± 184 and 125 ± 54 μM, resp.). This result may be related to the limiting effect of diffusion across the unstirred layer of medium when high V_{max} conditions are operating. The kinetic data suggest that the inappropriately high iron uptake by specimens from the iron-overloaded patients is the result of the affinity for iron being increased in a carrier in the enterocyte.

7075 HEPATIC ADENOMA AND ORAL CONTRACEPTIVES. (Fre.) Hureau, J.; Benit, C.; Delavierre, P.; Bourdais, J. P. (Hopital de Vaugirard, 389, rue de Vaugirard, 75015 Paris, France). *J. Chir. (Paris)* 114(5):339-350; 1977.

A case of hepatic adenoma in a 31-yr-old woman who had been taking oral contraceptives continuously for 10 yr is reported, and the alarming increase of this rare tumor in recent years is discussed. The preoperative diagnosis is fairly easy when hepatic arteriography, radioisotopic scan, and echotomography are combined with radiologic examinations of neighboring organs. Treatment consists of surgical removal of the affected segment and should not be delayed, since painful intratumoral bleeding often occurs. Cataclysmic hepatic hemorrhaging that results when the tumor ruptures externally is responsible for a death rate of 15.9%. Although not conclusively proven, mestranol appears to be the culpable ingredient in oral contraceptives, since 93.1% of women with hepatic adenomas have taken it, whereas only 44.8% of a control group free of hepatic lesions had been given a mestranol preparation. A review of the clinical, pathological, and pathogenic aspects of hepatic adenomas is given.

7076 RADIO- AND ENZYMEIMMUNOASSAY OF SERUM ALPHA-FOETO-PROTEIN IN SECONDARY CANCER OF THE LIVER. (Eng.) Masseyeff, R.; Rey, J. F.; Maiolini, R.; Krebs, B.; Delmont, J. (Laboratoire d'Immunologie, U.E.R. de Medecine, Chemin de Vallombrose, 06000 Nice, France). *Rend. Gastroenterol.* 9(2):91-96; 1977.

Serum alpha fetoprotein (AFP) was quantitated in 97 patients with secondary liver cancer, and radioimmunoassay (RIA) and enzyme-immunoassay (EIA) were compared for their efficacy in this determination. EIA and RIA gave similar results, with a correlation coefficient of 0.98 at $p \geq 0.001$. Twenty-three patients had AFP levels of 10 ng/ml or greater. Seven patients had levels >100 ng/ml, the highest being 610 ng/ml. Of the 23 patients with abnormal AFP levels, 45% had the primary tumor in the stomach, whereas only 20% of the 74 patients with normal AFP levels had primary stomach cancer. Further studies are needed to determine whether the site of abnormal AFP production in secondary liver cancer is the primary tumor, the metastatic tumor, or the area surrounding the metastasis. The close correlation between the results of EIA and RIA suggest that they can be used interchangeably, but EIA is a simpler and faster procedure.

7077 CLINICAL AND THERAPEUTIC ASPECTS OF HEPATOCELLULAR CARCINOMA. (Eng.) Johnson, P. J.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5, England). *Trans. R. Soc. Trop. Med. Hyg.* 71(6):462-465; 1978.

Hepatocellular carcinoma (HC) is reviewed. It is a major problem in certain parts of the Third World, but much less common in the West. In all areas of the world, about 70% of patients with HC have underlying cirrhosis, but the relationship between the two is not clear. Hepatitis B virus and aflatoxin have been suggested as carcinogenic environmental agents. Men are more susceptible to malignant change than are women, and the risk of such change increases with age. Both benign and malignant tumors have been associated with the contraceptive pill. The commonest modes of presentation are persistent right-sided upper abdominal pain and general deterioration in a patient with underlying cirrhosis. Routine liver function tests seldom permit discrimination of HC and cirrhosis, but α-fetoprotein determinations are a valuable discriminatory test, as levels rarely exceed 500 mg/ml in benign liver disease, but are >1,000 mg/ml in HC, and about 70% of HC cases will be positive by this criterion. Hepatic scintiscanning is useful in showing the extent of the lesion. Pathological confirmation is desirable, and this is usually obtained by percutaneous liver biopsy via a right lateral approach. The use of laparoscopy varies widely, but can be of value in selected cases, particularly in determining whether there is peritoneal spread. Hepatic arteriography is of diagnostic value in demonstrating the characteristic appearances of an abnormal vascular pattern when other tests have been inconclusive and in determining the extent of the tumor and its relation to the arterial supply and lobes of the liver. Management depends upon the extent of the tumor and on whether there is underlying cirrhosis. Resection may be undertaken when there is no cirrhosis; up to 7/8 of the liver may be removed. Hepatic artery ligation is useful in relieving pain and shrinking the tumor mass, but may only be used if there is no cirrhosis. In patients without metastasis, liver transplantation may be attempted. When metastases are present or the patient is otherwise too ill for surgery, chemotherapy is the only available approach, and various regimens have been used with varying success.

7078 LIVER METASTASES DISCOVERED DURING HIGH-DOSE EXCRETORY UROGRAPHY. (Eng.) Brennan, R.; Cossrow, J.; Pollack, H. (Thomas Jefferson Univ. Hosp., Philadelphia, PA 19107). *Radiology* 127(2):373-375; 1978.

The detection of hepatic metastases during excretory urography with tomography (EUT) is documented. The discovery of one such case prompted a retrospective review of the records of 106 patients who had had focal hepatic defects on ^{99m}Tc-labeled sulfur colloid liver scans; 18 were found to have had EUT that also included the posterior third to one-half of the right lobe of the liver on the tomograms. Of these 18, 3 had one or more liver masses visualized by EUT as round, lucent, hepatic filling defects during total body opacification. Radiologists performing high-dose EUT should routinely scrutinize the hepatogram because metastases, cysts, or abscesses may be visualized. Final diagnosis of such masses usually depends on additional diagnostic modalities.

7079 PERCUTANEOUS EMBOLIZATION FOR THE MANAGEMENT OF HEPATIC ARTERY ANEURYSMS. (Eng.) Goldblatt, M.; Goldin, A. R.; Shaff, M. I. (Groote Schuur Hosp., Observatory, Cape Town 7925, South Africa). *Gastroenterology* 73(5):1142-1146; 1977.

The cases of three patients who were treated for hepatic artery aneurysms with percutaneous embolization are presented. The first patient was a 55-yr-old woman who presented with hematemesis and debility. Celiac axis arteriography demonstrated a large tortuous aneurysmal sac arising from a branch of the left hepatic artery. Superselective embolization was carried out by injecting pledgets of gelfoam suspended in contrast medium. Celiac arteriography 7 weeks after embolization demonstrated no recurrence of the aneurysm. The second patient, a 30-yr-old male schizophrenic receiving phenothiazines, presented with hematemesis, melena, jaundice, pyrexia, epigastric tenderness, and elevated WBC count. The presence of a pyogenic abscess was suggested by ultrasound and confirmed by examination of a biopsy specimen taken at surgery. Hemoperitoneum and hematobilia were present with the biliary tree grossly distended by a blood clot and a small necrotic hemorrhagic area present in the left lobe of the liver. Celiac arteriography revealed gross extravasation of contrast medium into a cavity in the left lobe. Selective catheterization and embolization of the left hepatic artery controlled the extravasation, and no further bleeding occurred. The third patient, a 17-yr-old boy, was found to have a false aneurysm arising from a small proximal branch of the right hepatic artery following an abdominal gunshot wound. Embolization using autologous clot via a superselective coaxial catheter resulted in occlusion of the small feeding vessel. Experience with these cases suggests that embolic therapy may be the method of choice for hepatic artery aneurysms.

7080 FAMILIAL AND NONFAMILIAL BENIGN RECURRENT CHOLESTASIS DISTINGUISHED BY PLASMA DISAPPEARANCE OF INDOCYANINE GREEN BUT NOT CHOLYLGLYCINE. (Eng.) Van Berge-Henegouwen, G. P.; Ferguson, D. R.; Hofmann, A. F.; De Pagter, A. G. F. (St. Radboud Hosp., Nijmegen, Netherlands). *Gut* 19(5):345-349; 1978.

To determine whether a defect in uptake of organic anions is present in patients with benign recurrent cholestasis, the plasma disappearance of simultaneously injected indocyanine green and cholylglycine-1-^{14}C was measured in eight patients with asymptomatic benign recurrent cholestasis, 4 with the familial type, as well as 22 healthy control subjects. Evans blue was also simultaneously injected to permit correction for variation in blood volume and speed of mixing. Indocyanine green uptake was decreased in all three patients with definite nonfamilial benign recurrent cholestasis, but was normal increased in the four patients with the familial form of the disorder. By contrast, cholylglycine-1-^{14}C uptake was abnormal in one patient with each type of the disorder. Thus, patients with nonfamilial benign recurrent cholestasis have a defect in indocyanine green uptake, and patients with benign recurrent cholestasis are heterogeneous with respect to organic anion uptake.

7081 FREQUENCY OF INTRAHEPATIC ARTERIOVENOUS FISTULA AS A SEQUELA TO PERCUTANEOUS NEEDLE PUNCTURE OF THE LIVER. (Eng.) Okuda, K.;

Musha, H.; Nakajima, Y.; Takayasu, K.; Suzuki, Y.; Morita, M.; *et al.* (Chiba Univ. Hosp., Chiba, 280, Japan). *Gastroenterology* 74(6):1204-1207; 1978.

The incidence of intrahepatic arteriovenous fistula after needle biopsy of the liver, percutaneous transhepatic cholangiography, and transhepatic catheterization of an intrahepatic bile duct or portal vein was determined by studying the hepatic arteriograms obtained within 1 month of the transhepatic procedure. An arteriovenous fistula, mostly arterioportal, occurred in 5 of the 93 patients after biopsy, in 3 of 79 after percutaneous transhepatic cholangiography, and in 7 of 26 after catheterization. None of the fistulae was so large and close to the porta hepatis as to cause portal hypertension. In one patient with an intrahepatic bile duct carcinoma, the long track of a 0.7-mm caliber needle became a fistula draining arterial blood into the parenchyma. In another, an aneurysm was found after biopsy and percutaneous transhepatic cholangiography. A small intrahepatic fistula may seal itself. A tissue defect in the liver parenchyma may eventually be filled by regenerating liver cells or the canal may be distorted and interrupted by tissue regeneration.

7082 PERFUSION VASCULARITY MISMATCH IN LIVER HEMANGIOMAS. (Eng.) Front, D.; Hardoff, R.; Israel, O.; Schneck, S. O. (Rambam Medical Center, Haifa, Israel). *Clin. Nucl. Med.* 3(6):212-213; 1978.

Three cases of large cavernous hepatic hemangiomas in which a perfusion defect in the dynamic study and slow filling of the lesion by a blood pool agent were observed are presented. This finding is explained by the low perfusion and the large blood volume of cavernous hemangiomas. When such a lesion is suspected, a late blood-pool study should be performed to demonstrate the true vascularity of the lesion.

7083 HEMOPERITONEUM FROM SPONTANEOUS RUPTURE OF HEMANGIOMA OF THE LIVER, THE VALUE OF ANGIOGRAPHIC DIAGNOSIS: A CASE REPORT. (Eng.) Nyman, U. (Malmo General Hosp., S-214 02 Malmo, Sweden). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 128(2):237-238; 1978.

A case of spontaneous rupture of a liver hemangioma in which angiography was used as a diagnostic procedure is presented. The patient, a 37-yr-old man, was hospitalized in shock, and the peritoneal cavity was found at laparotomy to be filled with blood originating from a ruptured hemangioma on the lower border of the left lobe of the liver. The hemorrhage was controlled by suturing, but the lesion could not be excised. The exact site and extention of the hemangioma was demonstrated by angiography 2 days later, thereby facilitating proper surgical removal of the bleeding source.

7084 FATAL INTRAHEPATIC HEMORRHAGE AFTER PERCUTANEOUS LIVER BIOPSY USING A MENGHINI NEEDLE: A RARE BUT REAL COMPLICATION. (Eng.) Whittle, T. S., Jr. (Veterans Admin. Hosp., 109 Bee St., Charleston, SC 29403). *South. Med. J.* 70(11): 1355-1356; 1977.

A case of fatal intrahepatic hemorrhage in a 62-yr-old woman following percutaneous liver biopsy with a Menghini needle is reported. The biopsy was done with a needle of intermediate caliber (1.2 mm) via a posterior transcostal approach. The first unsuccessful attempt was followed immediately by a second attempt with the recovery of an adequate core of tissue. The patient required meperidine hydrochloride after complaining of nausea and mild right upper quadrant pain. The patient died the day following the procedure. At autopsy, a large subcapsular hematoma involving the dome and lateral portion of the right lobe of the liver was present. There was 200 ml of freshly clotted blood within the peritoneal cavity. Sectioning the liver revealed an extensive intrahepatic subcapsular hematoma in communication with a hemorrhagic linear portal tract corresponding to the tract of the needle. This is the first known report of a fatal intrahepatic hemorrhage after percutaneous Menghini needle biopsy in a patient without a hemorrhagic diathesis or underlying liver disease.

7085 CIMETIDINE CHOLESTATIC JAUNDICE IN CHILDREN. (Eng.) Lilly, J. R.; Hitch, D. C.; Javitt, N. B. (Univ. Colorado Sch. Medicine, Denver, CO 80262). *J. Surg. Res.* 24(5):384-387; 1978.

Liver function tests, including serum bile acid determination, were carried out as part of a prospective clinical investigation of the efficacy of cimetidine therapy in children with peptic ulcer disease; the results in five patients, aged 14, 3, 2, 1.5, and 1 yr, are presented. The patients received cimetidine (20-30 mg/kg/day) i.v. or p.o., and the total daily amount was given in four to six equal increments. Two patients had pre-existing liver disease. In the latter patients, peak serum bilirubin levels occurred before the institution of cimetidine therapy. There was a second minor rise in one of these patients 14 days after treatment was started. In the other three patients, the bilirubin level was elevated 14, 37, and 16 days, resp., after the initiation of cimetidine; the maximum elevations were 1.8, 2.9, and 2.3 mg%, resp. Total serum bile acids increased eight- and ninefold in the patients with pre-existing liver disease after cimetidine was started. In the three patients with normal liver function, the maximum total serum bile acid reached 14, 32, and 34 μM on the 10th, 15th, and 4th days after the initiation of therapy, resp. The values fell below the original value in one patient with liver disease and remained somewhat above the original value in the other. The values returned to normal before or shortly after discontinuing the drug in the patients with normal hepatic function. Because transaminases in all patients remained within, or almost within, normal limits, the elevated serum bile acids may represent a transient cholestasis rather than a manifestation of liver cell necrosis.

7086 PORPHYRIA CUTANEA TARDA TREATED WITH LOW DOSES OF ANTIMALARIAL AGENTS: LIVER FINDINGS.

(Cze.) Chlumsky, J.; Dobias, J.; Chlumska, A.; Malina, L. (I. interni klinika lekarske fakulty hygienicke, Universita Karlova, Srobarova 50, 100 34 Praha 10, Czechoslovakia). *Cas. Lek. Cesk.* 116 (45):1404-1406; 1977.

The effectiveness of the antimalarial agent chloroquine (125 mg twice weekly for 3-8 months) was studied in 32 patients with porphyria cutanea tarda. All patients achieved complete clinical and metabolic remission. The chloroquine tolerance proved to be satisfactory, even though a transient increase in the serum transaminase activity pointed to a certain stress of the hepatic parenchyma. Hepatic morphology was studied in 29 patients; the treatment caused no morphological changes in 25/29 cases and deterioration in 4 (2 patients with chronic hepatitis, 1 patient with uncharacteristic changes, and 1 with fibrosis). Hepatological investigations supplemented by liver biopsy are useful for the determination of the optimal complex treatment of the underlying metabolic disorder. Concomitant liver cirrhosis and chronic hepatitis call for simultaneous liver function-supporting treatment.

7087 DIAGNOSIS AND TREATMENT OF STENOSES AND OBSTRUCTIONS OF THE INTRAHEPATIC BILE DUCTS.

(Ger.) Spieler, U.; Largiader, F.; Ammann, R. (Kantonsspital, CH-8091 Zurich, Switzerland). *Helv. Chir. Acta* 44(4):471-475; 1977.

The diagnosis and treatment of 15 patients with obstruction of the intrahepatic bile ducts are described. Malignant tumors were the cause of obstruction in 11 cases, sclerosing cholangitis in 3, and post-traumatic skrinkage of scar in 1. The preoperative diagnosis was established by percutaneous transhepatic cholangiography in eight cases, by endoscopic retrograde cholangiography in four, and by laparoscopy in three. The obstruction was in the region of the hepatic bifurcation in 14 cases and in the area of the left hepatic duct in 1 case. Resection of the hepatic bifurcation and hepatic lobe with hepaticojejunostomy was performed in one case, resection of the hepatic bifurcation with hepaticojejunostomy in four, hepaticojejunostomy according to Longmire in two, and bougienage with inner splinting of the bile duct in eight cases. The postoperative mortality was 26%. The results were good concerning the restoration of bile drainage after hepaticojejunostomy and inner splinting, and poor after Longmire's operation. Primary carcinoma involving the junction of the hepatic ducts may be regarded as resectable, if the proximal extension of the tumor is limited to below the second bifurcation of the intrahepatic bile ducts in both the right and left lobes and if the proper hepatic artery and portal vein are not invaded.

7088 LIGATION OF THE HEPATIC ARTERY.

(Pol.) Piotrowicz, W.; Ancyparowicz, S.; Kawalski, A. (Klinika Chirurgii Ogolnej CMKP, ul. Czerniakowska 231, 00-416 Warsaw, Poland). *Pol. Tyg. Lek.* 32(45): 1771-1774; 1977.

The literature on ligation of the hepatic artery is reviewed. The indications for ligation of the hepatic artery are hepatic trauma, bleeding liver tumors, and rupture of an aneurysm of the hepatic artery. Ligation of the hepatic artery with subsequent intra-arterial treatment with 5-fluorouracil has been applied successfully in the treatment of patients with liver tumors. The mortality of ligation of the hepatic artery is about 18%.

7089 LIGATURE OF A HEPATIC ARTERY FOR LIVER TUMOR.

(Fre.) de Montalier, H.; Boiselle J. C. (Hopital Bichat, 170, boulevard Ney, 75018 Paris, France). *Ann. Chir.* 31(8):711-718; 1977.

The palliative treatment of multiple liver tumors by ligature of the hepatic artery is reviewed, and two cases of hepatic artery ligature for multiple liver metastases from carcinoid tumors of the small intestine are presented. Both patients had severe symptoms of carcinoid tumors, with flush and diarrhea and high urinary levels of 5-HIA (409 and 68 mg/24 hr, resp.). The clinical symptoms disappeared immediately after surgery and the 5-HIA levels were lowered within 5 days (to 72.5 and 47.3 mg/24 hr, resp.). There were transitory perturbations in SGPT, prothrombin, and bilirubin levels, but the values normalized within 2 weeks. One patient was in excellent health 18 months later; the other died after a total remission lasting 20 months. A review of the literature reveals nine similar cases with total remissions beginning right after surgery; all patients were still in good health 10 weeks to 18 months later. When ligature of the hepatic artery was performed for other types of metastases and for multiple hepatomas, the mean survival of patients was not much improved (from 75 days to 4.5 months), but the clinical remission was often excellent. When local chemotherapy was associated with the surgery (usually 5-fluorouracil at 12 mg/k day for 20 to 45 days, infused into the distal end of the hepatic artery), remissions of up to 22 months have been obtained, but the results are stil too preliminary to determine the effectiveness of this combination treatment.

Hyperbilirubinemic States

7111 FACTORS INFLUENCING THE INCIDENCE OF NEONATAL JAUNDICE. (Eng.) Friedman, L.; Lewis, P. J.; Clifton, P.; Bulpitt, C. J. (Queen Charlotte's Hosp., London W6 0XG, England). *Br. Med. J.* 1(6122):1229-1300; 1978.

To determine whether maternal oxytocin infusion or other factors are related to the development of neonatal jaundice (peak plasma bilirubin ≥205 μM), the rate of neonatal jaundice was analyzed in 12,461 single births at one hospital during a 5-yr period. Maternal oxytocin administration was associated with jaundice in 15.3% of neonates, whereas jaundice occurred in only 12.1% of neonates whose mothers did not receive oxytocin ($p<0.001$). The effect of oxytocin infusion on jaundice was independent of gestational age at birth, sex, race, epidural anesthesia, method of delivery, and birth weight, each of which was itself significantly associated with neonatal jaundice ($p<0.001$). The effect of oxytocin, however, was small, producing a calculated mean increase in peak plasma bilirubin concentration of 8.6 μM (0.5 mg/100 ml); this excess was independent of sex and less than the effect of the baby being born 1 week early. The results show that both oxytocin and epidural anesthesia have a small effect on the incidence of neonatal jaundice, which fact probably explains the conflicting reports on the effects of these factors.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7112 FATAL HEPATIC NECROSIS IN ASSOCIATION WITH THE USE OF HYCANTHONE: A CASE REPORT. (Eng.) Buchanan, N.; Thatcher, C. J.; Cane, R. D.; Bartolomeo, B. (Baragwanath Hosp., Johannesburg, South Africa). *S. Afr. Med. J.* 53:257-258; 1978.

A case of fatal acute massive hepatic necrosis secondary to the administration of hycanthone is reported. An 11-yr-old boy presented with hematuria, and his urine was found to contain *Schistosoma hematobium* ova. Hycanthone (100 mg, i.m.) was administered. The next day the patient vomited, became jaundiced, confused, and restless, and then became agitated (promethazine hydrochloride, 25 mg, was given); treatment for hepatic failure was begun. The next day the patient lapsed into coma, had cardiac arrest and was resuscitated, and was treated for hyperkalemia. Four additional episodes of cardiac arrest ensued, and the child died. Autopsy revealed large areas of hemorrhage, ulceration, and polypoid granulations in the bladder and irregular mottling of the liver with alternating yellowish and dark areas. Histologically, the bladder had numerous bilharzia ova in all layers, and the liver showed acute massive necrosis of short duration. It was discovered that the child was hepatitis B surface antigen-positive without history of previous disease. Excluding underlying liver disease, which may require serological or biochemical assessment, is a chief problem that makes the correct and widespread use of hycanthone impracticable.

7113 OXACILLIN HEPATITIS: TWO PATIENTS WITH LIVER BIOPSY, AND REVIEW OF THE LITERATURE. (Eng.) Bruckstein, A. H.; Attia, A. A. (St. Luke's Hosp., 113th St. and Amsterdam Ave., New York, NY 10025). *Am. J. Med.* 64(3):519-522; 1978.

Hepatotoxicity associated with i.v. sodium oxacillin therapy is reported in two drug abusers cured of staphylococcal endocarditis. One patient received 16 g oxacillin daily, and the other 12 g. Coincident with the administration of oxacillin, marked increases in hepatic SGOT (up to 1,380 IU in the first patient, to 420 IU in the second) and SGPT (up to 1,164 IU in the first patient, to 367 IU in the second) were observed, and liver biopsy showed nonspecific hepatitis. Upon cessation of oxacillin therapy, liver enzyme values returned to(ward) normal. Other reports of oxacillin-associated changes in hepatic enzyme levels are reviewed; further observation of oxacillin-associated hepatotoxicity is warranted.

7114 HEPATITIS SYPHILITICA: A CLINICO-PATHOLOGICAL STUDY OF 25 CASES. (Eng.) Jozsa, L.; Timmer, M.; Somogyi, T.; Feher, J. (Natl. Inst. Traumatology, Budapest, Hungary). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):344-347; 1978.

Clinical and biochemical findings indicative of liver damage are reported in association with early syphilis. Of 175 patients with early untreated syphilis, 25 had laboratory tests indicative of hepatic damage (increased serum bilirubin levels, increased ESR, positive colloid lability, increased SGPT and SGOT activity, abnormal prothrombin time and BSP value, altered serum protein and Ig levels). Light microscopy of biopsy material from the 25 patients showed slight or severe liver damage in 23 cases. There was proliferation of endothelial and Kupffer cells; leukocyte and lymphocyte infiltration of the sinusoids, arteries, and veins; narrowing of the lumena of vessels; focal necrosis; destruction of the reticulin structure; periportal inflammation; and fibrosis. In 17 cases, treponemes were demonstrated in the biopsy. After 2 months of penicillin treatment, nearly all of these features had reversed and returned to normal. Four specimens were examined before treatment and two after treatment using electron microscopy. Reduced glycogen content was observed. The mitochondrial matrix contained abundant electrodense material. Lysosomes were increased in size and number. The endoplasmic reticulum was generally degranulated and tubularized. Intracellular edema and vacuolization were observed. Lipid vacuoles were occasionally seen. Treponemes were demonstrated. These changes reversed after penicillin therapy. It is concluded that in some cases of syphilis, a characteristic hepatitis occurs at an early stage of the disease.

7115 CONGENITAL SYPHILITIC HEPATITIS: A RADIONUCLIDE STUDY. (Eng.) Gates, G. F.; Stanley, P.; Gwinn, J. L.; Miller, J. H. (Children's Hosp., 4650 Sunset Blvd., Los Angeles, CA 90054). *Radiology* 128(1):163-164; 1978.

The case of a 2-month-old girl in whom congenital syphilitic hepatitis was discovered by skeletal roentgenography is presented. The patient had marked hepatosplenomegaly; an erythematous, desquamating rash on the thighs; anemia; and leukocytosis. The serum alkaline phosphatase level was 474 IU. Hepatic scintigraphy with ^{99m}Tc sulfur colloid showed no uptake in most of the liver, but there was marked splenic, bone marrow, and lung uptake. Skeletal radiographs showed periosteal elevation along the shafts of all the long bones and proximal tibial metaphyseal irregularities suggestive of congenital syphilis; this diagnosis was confirmed by a venereal disease research laboratories titer of 1:128 and a positive fluorescent treponemal antibody reaction. After a 10-day course of procaine penicillin, the liver and spleen sizes were decreased and there was improved liver uptake of radiocolloid with decreased spleen size, although bone marrow and lung accumulation persisted. A liver scan 6 months later was normal.

7116 INTRAHEPATIC CHOLESTASIS INDUCED BY DRUGS AND CHEMICALS. (Eng.) Plaa, G. L.; Priestly, B. G. (Faculte de Medecine, Universite de Montreal, C.P. 6128, Montreal, Quebec, Canada). *Pharmacol. Rev.* 28(3):207-273; 1977.

7117 PROTECTIVE EFFECTS OF NUTRITIONAL STATUS ON DRUG-INDUCED FATTY LIVER AND HEPATOCELLULAR NECROSIS [Abstract]. (Eng.) Sabesin, S. M.; Kinnard, M. S. (Univ. Tennessee Center Health Sciences, Memphis, TN). *Gastroenterology* 72(5, Part 2):1124; 1977.

7118 HEPATOTOXICITY OF COMBINATION CHEMOTHERAPY FOR ACUTE MYELOCYTIC LEUKEMIA [Letter to Editor]. (Eng.) Penta, J. S.; Von Hoff, D. D.; Muggia, F. M. (Natl. Cancer Inst., Bethesda, MD 20014). *Ann. Int. Med.* 87(2):247-248; 1977.

Acute Viral Hepatitis

7119 A NEW HUMAN HEPATITIS VIRUS. (Eng.)

Zuckerman, A. J. (London Sch. Hygiene and Tropical Medicine, London, England). *Nature* 271 (5641):113-114; 1978.

Evidence for the existence of a third type of human viral hepatitis is reviewed. The identification of specific viral antigenic markers of hepatitis A (HA) and hepatitis B (HB) permits specific diagnosis and has lead to the recognition of a third form of hepatitis unrelated to either HA or HB, referred to in the United States as non A, non B hepatitis (NANBH). NANBH is now the most common form of hepatitis occurring after blood transfusion in some areas of the world. Serum samples from five blood donors implicated in the transmission of post-transfusion hepatitis, which had been stored frozen since the 1950s, were tested; two of the donor sera contained HB virus and transmitted HB to all susceptible recipients, two of whom developed hepatic coma. The remaining three sera did not contain HB markers but nevertheless transmitted a form of hepatitis to nine volunteer recipients that could not be attributed to HA virus (HAV), HB virus (HBV), cytomegalovirus, or Epstein-Barr virus (EBV). The incubation period ranged from 18-89 days, and the clinical illness was similar to HB. Two volunteers developed evidence of persistent liver damage. In a separate study, 16 of 44 patients with NANBH had persistent biochemical evidence of liver damage 6 months after the acute illness; in 10 patients, the abnormality persisted 1-3 yr, and liver biopsy revealed histological evidence of chronic liver damage. It was further observed that 9/22 patients who received placebo (albumin solution) developed evidence of chronic hepatitis, whereas only 1/11 who received normal Ig and 0/11 who received HB Ig did so. When the cause of acute hepatitis was investigated in 45 patients at one hospital, 20 had no laboratory evidence of infection with HAV, HBV, cytomegalovirus, or EBV. It was noted that in nearly half of these patients, the infection followed the type of exposure traditionally associated with HB infection. These reports suggest that (1) a carrier state of NANBH exists, (2) infection must be common since pooled Ig seems to contain prophylactic activity, and (3) this infection may progress to chronic liver disease. There is an urgent need to develop specific laboratory tests for identifying the virus or viruses involved.

7120 FULMINANT HEPATITIS: REVIEW OF 137 CASES. I. COMPLICATIONS. (Fre.)

Nusinovici, V.; Crubille, C.; Opolon, P.; Touboul, J. P.; Darnis, F.; Caroli, J. (Hopital Saint-Antoine, 184, rue du Faubourg-Saint-Antoine, F 75012 Paris, France). *Gastroenterol. Clin. Biol.* 1(11):861-873; 1977.

The principal complications in a series of 137 patients in grade IV coma resulting from fulminant hepatitis are discussed. The etiology of the hepatitis was viral in 85% of cases and drug related (especially isoniazid) in 8%. Upper digestive tract hemorrhages occurred in 39% of patients, with 48% of patients who received corticosteroids hemorrhaging, whereas only 27% of patients not treated with steroids hemorrhaged ($p<0.02$). Cerebral edema was difficult to demonstrate clinically, but was present in 24% of necropsied patients; treatment with furosamid and/or mannitol did not seem to improve the edema. Severe hyperlactatemia with acidosis and hypocapnia was seen in 9% of the patients; its evolution was always fatal. Hyperamylasemia was present in 53% of the patients. In 19% of necropsied patients, macroscopic pancreatic lesions could be observed. Plasmatic and globular hypovolemia, which was refractive to transfusions, was present in 47% of the patients. Proteinuria (>0.50 g/24 hr) was observed in 30% of the patients. Creatinemia >15 mg/l was found in 26/35 patients tested; all of these died, whereas 7/9 patients with creatinine of <15 mg/l survived. Septicemia developed in 20% of patients and it was fatal in 6%. Overall mortality was 82.5% in spite of symptomatic treatment (maintenance of hydroelectrolytic and volumetric equilibrium, assisted ventilation, total transfusions, and the administration of human albumin, furosamid, lactulose, and anticonvulsants) and curative treatment (corticotherapy, hemodialysis, perfusions with coenzyme A, and administration of plasma rich in anti-HBs antibodies).

7121 FULMINANT HEPATITIS WITH COMA: A REVIEW OF 137 CASES. II. COURSE AND PROGNOSIS.

(Fre.) Nusinovici, V.; Crubille, C.; Opolon, P.; Touboul, J. P.; Darnis, F.; Caroli, J. (Hopital Saint-Antoine, 184, rue du Faubourg-Saint-Antoine, F 75012 Paris, France). *Gastroenterol. Clin. Biol.* 1(11):875-886; 1977.

Experience with 137 cases of fulminant hepatitis is reviewed. Fulminant hepatitis led to death in 82.5% of the cases. Etiology did not influence the outcome of the disease. Of statistical significance in predicting the prognosis were age (average age of the 24 survivors was 29 ± 11 versus 38 ± 16 in the 113 fatalities, $p<0.02$), depth of coma ($p<0.001$), convulsions ($p<0.01$), gastrointestinal bleeding ($p<0.001$), creatinemia (14 ± 5 mg/l in survivors versus 38 ± 26 mg/l in fatalities, $p<0.02$), urinary urea (20 ± 12 g/24 hr versus 12 ± 9 g/24 hr, resp., $p<0.01$), hypocapnia ($p<0.05$), galactose clearance ($p<0.05$), prothrombin time ($p<0.02$), factor V level ($p<0.001$), fibrinogen level ($p<0.02$), ethanol test ($p<0.05$), von Kaulla's test ($p<0.01$), and hepatocyte volume ($p<0.05$). The principal causes of death were decerebration (50%), hemorrhage (17.6%), cardiovascular collapse (11.5%), and sepsis (6%). Hepatic regeneration was present in 17 patients at the time of death, but the causes of death in these patients did not differ significantly from those of other patients. When patients received hemodialysis with a polyacrylonitrile membrane, they regained consciousness significantly more often than did nondialyzed patients (6/13 vs 5/96, $p<0.001$). In the latter patients, transient consciousness was always accompanied by liver regeneration. Hemodialyzed patients also lived longer in a coma than did nondialyzed patients (7.6 ± 6 days versus 3.9 ± 2.6 days, $p<0.02$). The overall survival rate was only 17.5% and was not influenced by the type of treatment. Of the 24 survivors, 21 were completely healed after a few months, 1 had chronic hepatitis, and 1 had acute chronic hepatitis.

7122 HEPATITIS IN CLINICAL LABORATORIES 1975-76. (Eng.) Grist, N. R. (Ruchill Hosp., Glasgow G20 9NB, England). *J. Clin. Pathol.* 31(5): 415-417; 1978.

The survey of British laboratories in 1970-74 was continued by a questionnaire to members of the Association of Clinical Pathologists covering the next 2 yr. Only nine cases of hepatitis (3 of hepatitis B) were reported in a total of 223 laboratories. The annual attack rate of 34 per 100,000 was only one-fourth that reported in the previous 2 yr. No laboratory reported more than a single case, and an analysis of the characteristics and work patterns of the laboratories showed no special association with hepatitis. The dramatic fall in the attack rate of hepatitis since the previous study, and in particular of hepatitis B, suggests that the strenuous and expensive efforts in recent years to prevent laboratory-acquired hepatitis in Britain have had considerable success.

7123 HEPATITIS: THE PLIGHT OF THE CARRIER. (Eng.) Blumberg, B. S. (Univ. Pennsylvania, Philadelphia, PA). *Sciences* 8(3):10-11, 30; 1978.

The social consequences of the existence of simple routine tests for the detection of hepatitis B surface antigen (HBsAg) carriers are discussed. The carrier state is usually detected in an asymptomatic individual whose serum is tested for routine blood donation. The carrier is unique in that he is asymptomatic but may unwittingly cause illness in others. It is not known how many carriers can transmit hepatitis by means other than transfusion; although there are cases of this type, they appear to be rare. Some evidence has suggested that carriers who have evidence of ongoing liver disease or who have the e antigen are more likely to transmit the disease. Problems faced by health care personnel, Vietnam veterans, and orphaned Vietnamese children brought to the United States who are carriers are discussed. The value of taking measures to isolate these carriers is questioned: should one group of carriers be stigmatized while others are not, just because it is easy to unmask them?

7124 THE RISK OF HEPATITIS B TO HOSPITAL PERSONNEL: A PROSPECTIVE STUDY AMONG PERSONNEL EXPOSED TO PATIENTS WITHOUT ISOLATION PRECAUTION. (Eng.) Wickliffe, C. W.; Galambos, J. T.; Rivers, S.; Blitch, L. (Emory Univ. Sch. Medicine, 69 Butler St. S.E., Atlanta, GA 30303). *Am. J. Dig. Dis.* 23(4):293-296; 1978.

A study was undertaken to determine prospectively the probability of developing clinical or serological evidence of hepatitis B virus infection among ward personnel involved in the care of hepatitis B patients where no specific isolation precautions were in use other than separate collection of hypodermic needles and no parenteral exposure occurred. During a 2-week period, 54 ward personnel were exposed to 2 patients with severe type B hepatitis, one with fulminant hepatitis who died on the fifth hospital day and one with grade 2 encephalopathy who was on the ward for 10 days. Both patients were hepatitis B surface antigen (HBsAg)-positive. The 54 subjects were categorized by exposure to the 2 patients: group A, physcial contact with the index cases >3 times (n=15); group B, physical contact <3 times (n=15); group C, physical contact with containers of blood, feces, urine, or saliva from index cases (n=11); and group D, no physical contact, but on the ward with index cases (n=13). Clinically recognizable hepatitis did not develop among the 54 subjects during 22 weeks of follow-up; all remained negative for HBsAg. Two from group B and two from group D developed mild transient SGPT elevations; antibody to HBs (anti-HBs) was negative in all four subjects. Anti-HBs was demonstrated in 7/54 subjects (3 in group B, 1 in group C, and 3 in group D); 5/7 had been anti-HBs-positive initially (at 1 week), whereas 2 became positive later (at 3 and at 13 weeks). This study indicates that ward personnel who care for patients with type B hepatitis are not at an increased risk of infection when specific isolation procedures are not used.

7125 HEPATITIS B: ABSENCE OF TRANSMISSION BY GASTROINTESTINAL ENDOSCOPY. (Eng.) McClelland, D. B. L.; Burrell, C. J.; Tonkin, R. W.; Heading, R. C. (Royal Infirmary, Edinburgh, Scotland). *Br. Med. J.* 1(6104):23-24; 1978.

To evaluate the risk of transmitting hepatitis B via a contaminated endoscope, 37 of 38 patients examined with the same instrument after it was used to examine a man with persistent hepatitis B (HB) antigenemia were followed up. The index patient was HB surface antigen (HBsAg)- and HBeAg-positive at the time of his endoscopy, but the discovery was made too late to prevent the further use of the instrument for 15 days. Between examinations, the instrument was cleaned only with water, chlorhexidine, and cetrimide. Sera from 37 patients were obtained 2-104 days after endoscopy and were all HBsAg- and HBeAg-negative; 2 were positive for antibody to HBsAg (anti-HBs). Thirty patients were retested at 162-225 days with no antigenemia detected and no change in antibody titers found. Using an ^{125}I-HBsAg marker, contamination of instruments was simulated, and washing procedures usually employed were followed; it was possible to recover the marker from the instruments after the routine cleaning. The coiled outer cover of the forceps was a particularly important trap for contaminated material. Although the results suggest that this mode of transmission of HB is rare, additional precautions are suggested for decontaminating instruments. Known HBsAg carriers should be examined with separate instruments for which there are separate precautions.

7126 A CASE OF HEPATITIS B WITH PLEURAL EFFUSION. (Eng.) Flacks, L. M.; Lees, D. (Rotorua Hosp., Rotorua, New Zealand). *Aust. N.Z. J. Med.* 7(6):636-637; 1977.

A case of viral hepatitis B with associated large pleural effusion is reported. The patient was a 26-yr-old man. Pleuritic pain and effusion developed on day 6 of his illness; jaundice was observed on day 9. Increased awareness of the association between viral hepatitis and pleural effusion seems to be of clinical importance and may contribute to knowledge of autoimmune phenomena and the part they play in the interrelationship of certain diseases.

7127 HEPATITIS IN HEMODIALYSIS PATIENTS: SIGNIFICANCE OF HBeAg. (Eng.) Miller, D. J.; Williams, A. E.; Le Bouvier, G. L.; Dwyer, J. M.; Grant, J.; Klatskin, G. (Yale Univ., Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *Gastroenterology* 74(6):1208-1213; 1978.

Twenty-four hepatitis B surface antigen (HBsAg)-positive (HBsAg$^+$) hemodialysis patients were prospectively studied to assess (1) the prognostic value of hepatitis B e antigen (HBeAg) and its HBe$_1$Ag and HBe$_2$Ag components and (2) whether a difference in cellular immune status between HBeAg$^+$ and HBeAg$^-$ negative (HBeAg$^-$) patients could be defined. Sixteen patients were HBeAg$^+$ and eight were HBeAg$^-$ initially. After a mean follow-up period of 23.7 months, 15 of the 16 HBeAg$^+$ patients were still HBsAg$^+$ at death or last follow-up, whereas 7 of the 8 HBeAg$^-$ patients had become HBsAg$^-$ at a mean period of 3.8 months. This finding indicates that the initial presence of HBeAg correlates with HBsAg persistence. HBe$_1$Ag was consistently present in 15 of the 16 patients when HBeAg was detectable, whereas HBe$_2$Ag fluctuated widely in individual patients over time. No difference in cellular immune status between HBeAg$^+$ and HBeAg$^-$ patients could be defined; although both HBeAg$^+$ and HBeAg$^-$ patients had a similar decrease in peripheral blood thymus-derived cells and poor responsiveness to purified HBsAg, both groups of patients had stimulation indices to nonspecific mitogens within the normal range.

7128 CYTOMEGALOVIRUS HEPATITIS (DIAGNOSIS AND DIFFERENTIAL DIAGNOSIS). (Eng.) Groza, S. (Faculty Medicine, Univ. Belgrade, Belgrade, Yugoslavia). *Acta Hepatogastroenterol. (Stuttg.)* 24(5):340-343; 1978.

The diagnosis and differential diagnosis of cytomegalovirus (CMV) hepatitis is considered. A 12-yr-old girl presented with fever, nausea, and vomiting. Her sclerae were subicteric, the glands in her neck were mildly enlarged, and she had predominantly mononuclear cells in the peripheral blood. Biochemical analyses did not indicate hepatitis A. The patient's sclerae cleared on the third hospital day, and she became afebrile; there were no complications and the disease had a mild course. Histological analysis revealed viral hepatitis in an advanced stage. Virological examination of the patient's serum confirmed the CMV etiology of the disease. An accurate diagnosis could not have been made without the virological results.

7129 SERUM BILE ACIDS IN PATIENTS WITH VIRAL HEPATITIS. (Eng.) Pennington, C. R.; Ross, P. E.; Bouchier, I. A. D. (Ninewells Hosp. and Medical Sch., Dundee, Scotland). *Scand. J. Gastroenterol.* 13(1):77-80; 1978.

To evaluate the changes in the total and individual bile acids in patients with viral hepatitis, fasting blood samples were obtained from 18 patients when they were first seen. In 9/18 patients (group A) who were seen within 2 weeks of the onset of symptoms, fasting serum was also obtained at weekly intervals for 2 more weeks. In 8/18 patients (group B) postprandial serum bile acids were estimated during convalescence every 2 weeks until liver function tests had returned to normal. Total serum bile acid values for the 18 patients were 42.9-452 μM (normal maximum is 4.5 μM), which values correlated with the serum bilirubin levels ($r=0.63$, $p<0.005$) but not with the aspartate aminotransferase (AAT) levels. Cholic (C), chenodeoxycholic (CD), and deoxycholic (D) acids were the major bile acids in the 18 patients; their proportions were variable (e.g., C:CD was 0.19-1.91); D accounted for only 5.1% of the total compared to 26.1% in control subjects ($p<0.001$). In group A, the C:CD ratio tended to increase with time, as C replaced CD in predominance as the disease resolved. When compared to the levels of bilirubin, AAT, and γ-glutamyl-transpeptidase, the levels of postprandial serum bile acids returned to the normal range at varying times. It is concluded that the measurement of serum bile acids does not provide added information of value in the management of patients with viral hepatitis.

7130 SERUM MYOINOSITOL AND PHOSPHATIDYLINOSITOL IN PATIENTS WITH VIRAL HEPATITIS. (Pol.) Tkaczewski, W.; Tkacz, B.; Lutz, W.; Szeszko, A.; Dworniak, D.; Drobnik, S. (Instytut Medycyny Wewnetrznej WAM, ul. Kniaziewicza 1/5, 91-347 Lodz, Poland). *Pol. Tyg. Lek.* 32(49):1913-1915; 1977.

The serum concentrations of myoinositol, phosphatidylinositol, cholesterol, and total phospholipids as well as the serum alanine aminotransferase activity were determined in 17 patients with serum hepatitis during the 1st, 2nd, 3rd, and 4th weeks of the disease. The myoinositol levels were 51.6 ± 10.7 μM during the 1st week ($p<0.001$) and 34.9 ± 8.2 μM during the 2nd week ($p<0.02$) versus a normal value of 21.5 ± 5.5 μM. There was no significant difference during the 3rd and 4th weeks. The phosphatidylinositol levels were 126 ± 21 µM during the 1st week ($p<0.001$), 153 ± 24 µM ($p<0.001$) during the 2nd week, 186 ± 35 µM ($p<0.005$) during the 3rd week, and 199 ± 36 µM ($p<0.01$) during the 4th week, compared with a normal level of 255 ± 42 µM. The cholesterol and total phospholipid levels did not show any significant change from the respective normal values. The alanine aminotransferase activity dropped sharply from the 1st to the 4th week.

7131 SEROCONVERSION FROM HEPATITIS B e ANTIGEN TO ANTI-HBe IN ACUTE HEPATITIS B VIRUS INFECTION. (Eng.) Aikawa, T.; Sairenji, H.; Furuta, S.; Kiyosawa, K.; Shikata, T.; Imai, M.; *et al.* (Mito Natl. Hosp., Ibaraki-ken, Tokyo, Japan). *N. Engl. J. Med.* 298(8):439-441; 1978.

To study the temporal course of hepatitis B e antigen (HBeAg) and antibody to it (anti-HBe), a recently developed sensitive passive hemagglutination assay was used to investigate sera from persons at high risk of HB infection and from a chimpanzee with experimental HB infection. HB was diagnosed in seven members of the medical staffs of two laboratories conducting research with HB virus, and a chimpanzee was inoculated with 0.1 µl of pooled plasma from HB carriers containing both HBeAg-associated and HB surface Ag (HBsAg)-associated DNA polymerase activity. HBeAg was present (titer 2^3-2^{10}) in all sera as long as HBsAg was present. After recovery from hepatitis, anti-HBe developed in the sera of three patients and of the chimpanzee but was not found in the remaining sera during 10 weeks of follow-up. Antibody to HBsAg (anti-HBs) developed in six patients and the chimpanzee; antibody to HB core antigen (anti-HBc) developed in all sera. All subtypes of HBsAg were present and bore no relation to the appearance of HBeAg. The time courses for the antigens and antibodies in one patient and the chimpanzee are given. It is possible that the seroconversion to anti-HBe could have occurred at a level below the lower limit of the detection method in the four patients not found to become anti-HBe-positive. However, seroconversion to anti-HBe does occur in acute HB infection.

7132 IgA DYSGAMMAGLOBULINEMIA IN LIVER DISEASES. (Cze.) Svejda, J.; Richter, J. (Infekcni oddeleni, Krajska nemocnice s poliklinikou KUNZ, tr. SNP 18, 400 11 Usti nad Labem, Czechoslovakia). *Cas. Lek. Cesk.* 117(4):111-114; 1978.

Various dysgammaglobulinemias were found in 28/282 patients with viral hepatitis and diseases of the gallbladder and bile ducts. IgG dysgammaglobulinemia was found in one patient with hepatitis A and another with hepatitis B. IgA dysgammaglobulinemia was found in two patients with hepatitis A and in two patients with hepatitis B. IgM dysgammaglobulinemia was found in 2 patients with hepatitis A, in 9 patients with hepatitis B, and in 10 patients with diseases of the gallbladder and bile ducts. IgG paraprotein was found in one patient with hepatitis B. The IgA levels were 0.004-0.370 IU/ml in three of the four patients with IgA dysgammaglobulinemia 12-24 months after viral hepatitis and were absent in the fourth patient. The conspicuously high incidence of dysgammaglobulinemias is interpreted as a sign of predisposition among patients with this condition to viral hepatitis and diseases of the gallbladder and bile ducts.

7133 HEPATITIS IN EARLY SYPHILIS: REPORT OF THREE CASES. (Eng.) McMillan, A.; Anderson, J. R.; Robertson, D. H. H. (Royal Infirmary, Edinburgh EH3 9YW, Scotland). *Br. J. Vener. Dis.* 53(5):295-298; 1977.

The cases of three patients with early syphilis and liver dysfunction, none of whom was known to have had contact with hepatitis, are presented. Two patients had had several homosexual contacts, but neither hepatitis B antigen nor antibody was detected in their sera. The first patient, a 38-yr-old man, presented with pruritus, nausea, dark urine, and scleral icterus. He had been examined 2 months earlier for syphilis, but his Venereal Diseases Research Laboratory (VDRL) and *Treponema pallidum* hemagglutination (TPHA) tests were negative. The patient had abnormal liver function tests and hepatomegaly. There was no evidence of a healed primary lesion or a rash, but the VDRL titer was positive at 1:8, and the TPHA titer was positive at 1:80; the fluorescent treponemal antibody absorption (FTA-ABS) test was also positive. Four days later, he developed a maculopapular rash. One week following the start of penicillin therapy, the rash faded, and the jaundice disappeared after 2 weeks. The second patient presented with typical condylomata lata in the perianal region and a papulosquamous rash but no evidence of a healed primary lesion. Tests for syphilis were positive. He was not jaundiced, but the liver enzymes were elevated. The liver function tests began to normalize 14 days after starting penicillin therapy and were normal 6 weeks later. The third patient, a 46-yr-old man, had a penile ulcer, no evidence of jaundice or mucocutaneous lesions of secondary syphilis, and no hepatomegaly. The liver function tests were abnormal. The patient was asymptomatic and liver function tests were normal 8 weeks after penicillin therapy. These cases emphasize the need to exclude syphilis when the liver function tests of a jaundiced patient do not conform to any well-defined pattern.

7134 HEPATITIS B IS NOT TRANSMITTED BY ORAL-FECAL ROUTE. (Fre.) Piazza, M.; Cacciatore, L.; Molinari, V.; Picciotto, L. (Faculty Medicine, Univ. Naples, via S. Pansini, Naples, Italy). *Nouv. Presse Med.* 6(29):2606-2607; 1977.

7135 PROGNOSTIC VALUE OF ISOENZYMES IN ACUTE HEPATITIS: LOADING TESTS. (Ger.) Baumgarten, R.; Klimmt, G.; Graubaum, H. J.; Wagenknecht, C. (Stadtisches Krankenhaus Prenzlauer Berg, Nordmarkstrasse 15, DDR-1055 Berlin, E. Germany). *Z. Gesamte Inn. Med.* 32(3):43-45; 1977.

7136 IMMUNOLOGICAL ASPECTS OF VIRAL HEPATITIS. (Ger.) Meyer zum Buschenfelde, K. H.; Arnold, W.; Hutteroth, T. H. (Klinikum Charlottenburg der Freien Universitat, Spandauer Damm 130, D-1000 Berlin 19, W. Germany). *Internist (Berlin)* 18(4):201-207; 1977.

7137 SERUM IMMUNOGLOBULIN LEVELS IN CHILDREN WITH VIRAL HEPATITIS. (Rus.) Makhmudova, O. S.; Mukhamedov, D. B. (Central Asiatic Inst. Pediatric Medicine, Tashkent, USSR). *Zh. Mikrobiol. Epidemiol. Immunobiol.* (8):140-141; 1977.

LIVER AND BILIARY TRACT

Chronic Hepatitis

7144 ISOENZYMES OF ASPARTATE AMINOTRANSFERASE IN CHRONIC LIVER DISEASES. (Eng.) Skrha, J.; Stepan, J.; Volek, V. (Faculty Medicine, Charles Univ., U nemocnice 1, 128 21 Prague 2, Czechoslovakia). *Acta Hepatogastroenterol. (Stuttg.)* 25 (2):127-129; 1978.

To evaluate the importance of aspartate amino transferase (AST) isoenzymes (cytoplasmic and mitochondrial) in liver diseases, the plasma levels of these isoenzymes were studied in 27 patients with chronic hepatitis, 23 with liver cirrhosis, 6 with focal liver tumors, and in 34 healthy controls. The patients were further divided as having biochemically active hepatitis (9) or cirrhosis (18) or stabilized hepatitis (12) or cirrhosis (6). The patients with active hepatitis or cirrhosis and with neoplasms had significantly higher total AST activity, cytoplasmic AST isozyme activity, and mitochondrial AST isoenzyme activity as compared with controls ($p < 0.005$), whereas those with stabilized hepatitis or cirrhosis had AST values similar to those of contro In particular, the mitochondrial AST levels in patients with neoplasms were markedly elevated. Thes results indicate the usefulness of mitochondrial AS determinations in estimating the depth of structura liver damage and the stability of a liver disease process.

7145 EFFECT OF VIDARABINE ON CHRONIC HEPATITIS B VIRUS INFECTION. (Eng.) Pollard, R. B.; Smith, J. L.; Neal, E. A.; Gregory, P. B.; Merigan, T. C.; Robinson, W. S. (Stanford Univ. Medical Center, Stanford, CA 94305). *JAMA* 239(16):1648-1650; 1978.

To evaluate the effect of vidarabine (adenosine arabinoside) on Dane particle markers in hepatitis B virus (HBV) infection, two patients with chronic hepatitis and HBV infection were studied. Both patients received two courses of vidarabine of 15 mg/kg/day for 9-14 days separated by an interval of 7 weeks in one patient and 20 days in the other. In the first patient, Dane particle DNA polymerase activity decreased markedly during each course and rose sharply when vidarabine therapy was stopped; in the second patient, the DNA polymerase activity fell to undetectable levels by day 8 of course one, rose somewhat in the interval, then fell again to undetectable levels during the second course and has remained undetectable for 12 months. No significant change occurred in the hepatitis B surface antigen (HBsAg) complement fixation titer in the first patient, but in the second patient, the titer fell from 1:256 to <1:8 and remained at this level for 12 months after therapy. The hepatitis B core antigen (HBcAg) level was transiently decreased in the first patient but became undetectable in the second patient after the second course. Mild transient suppression of granulocytes, reticulocytes, and platelets occurred in both patients during therapy. The first patient experienced nausea, anorexia, and constipation. The second patient had mild abdominal cramping during the first course of treatment that recurred with nausea and more notable cramping pain during the second course; since the patient was an insulin-dependent diabetic with autonomic neuropathy, the relative contribution of vidarabine to her signs and symptoms is uncertain. No consistent changes in liver function tests were observed in either patient. The reason for the differential response of the two patients is unknown. The results suggest that the replication of HBV may be inhibited by vidarabine, but the side-effects of this drug indicate that further study is required before it is used in therapy for HBV infection.

7146 PROGNOSTIC VALUE OF HBeAg IN CHRONIC PERSISTENT HEPATITIS. (Eng.) Pastore, G.; Dentico, P.; Fera, G.; Schiraldi, O. (Clinica Malattie Infettive Universita di Bari, Policlinico, 70124 Bari, Italy). *Br. Med. J.* 2(6101):1521; 1977.

The relationship between the hepatitis B e antigen/antibody (HBeAg/anti-HBe) system and the prognosis was studied in 35 patients with hepatitis B surface antigen (HBsAg) and antibody (anti-HBs)-positive chronic progressive hepatitis. Twelve patients, four of whom carried anti-HBe and two HBeAg, showed biochemical and histological resolution of liver disease over 12 months. The two patients with HBeAg lost the antigen after 6 and 7 months, resp. Fifteen patients showed no change during a mean of 24 months' observation. Five were anti-HBe carriers and six were HBeAg carriers. Only two of these six lost their initial HBeAg positivity despite persistence of HBsAg. Eight patients developed chronic aggressive hepatitis (6 cases) or cirrhosis (2) within 6 months to 3 yr. All eight had HBeAg in their serum, and only one showed seroconversion of HBeAg positivity. These data suggest that the loss of HBeAg in chronic progressive hepatitis may be an important prognostic sign indicating resolution of the illness. Persistence of HBeAg may be associated with an impaired immune response to the hepatitis B virus.

7147 CHRONIC ACTIVE HEPATITIS AND MEMBRANEOUS GLOMERULONEPHRITIS. (Eng.) Cogan, M. C.; Graber, M. L.; Connor, D. G. (Dept. Medicine, 1065 HSE, Univ. Southern California, San Francisco, CA 94143). *Am. J. Gastroenterol.* 68(4):386-391; 1977.

The case of a 26-yr-old man with hepatitis B surface antigen (HBsAg) in his serum for 5 yr who developed the nephrotic syndrome is presented. He was referred for evaluation due to increasing edema. His SGOT and SGPT were elevated (150 mU/ml and 62 mU/ml, resp.), the 24-hr urinary protein excretion was 3 g of which 77% was albumin, and the serum albumin was 2.8 g%. A percutaneous renal biopsy showed classic changes of membraneous glomerulonephritis (GN) with basement membrane thickening and "spikes" on silver methenamine staining. Electron microscopy showed large intramembraneous electron-dense deposits and podocyte "fusion." Immunofluorescent examination revealed a granular distribution of IgG and complement component C3 in the glomeruli and IgA in the interstitium. Indirect immunofluorescence showed HBsAg in a granular distribution in the glomeruli. A liver biopsy showed chronic active hepatitis (CAH) with widening of the portal tracts by mononuclear cell infiltrates, piecemeal necrosis of limiting plates, and focal bridging without cirrhosis. Prednisone therapy (100-120 mg every other day) brought the SGOT to 50 mU/ml after 4 months, but the hypoalbuminemia and proteinuria remained. The finding of HBsAg deposition in the glomerulus supports the pathogenic relation of the antigenemia to the renal disease.

7148 A CASE OF CHRONIC ACTIVE HEPATITIS WITH ANTIMICROSOMAL AND ANTINUCLEAR ANTIBODIES. (Ita.) Marchesini, G.; Masi, M.; Paolucci, P.; Franceschi, C.; Perocco, P.; Zauli, D. (Universita di Bologna, Istituto di Patologia Speciale Medica, Bologna, Italy). *Minerva Pediatr.* 29(12):827-832; 1977.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

7151 EPIDEMIOLOGICAL ASPECTS OF ALCOHOLIC LIVER CIRRHOSIS IN MEXICO.

(Spa.) Dajer, F.; Guevara, L.; Arosamena, L.; Suarez, G. I.; Kershenobich, D. (Instituto Nacional de la Nutricion, Av San Fernando y Viaducto Tlalpan, Mexico 22, D.F., Mexico). *Rev. Invest. Clin.* 30(1):13-28; 1978.

The epidemiology of alcoholic liver cirrhosis was studied in Mexico in a series of 2,394 cirrhotic patients during the period 1947-1975. Alcoholic liver cirrhosis was diagnosed in 55.7% of the patients, posthepatitic cirrhosis in 36.6%, cryptogenic cirrhosis in 5.8%, and other forms of cirrhosis in 1.9%. Men accounted for 93.75% of the patients with alcoholic liver cirrhosis. Nearly 80% of the patients had the first clinical manifestation of cirrhosis between the ages of 31 and 60 yr; alcoholic liver cirrhosis was diagnosed during the first year after the onset of the symptoms in 59.8% of the patients. The age at which the patients started drinking ranged from 3 to 63 yr. Seventy-eight percent of the patients were heavy daily drinkers. The alcohol was generally consumed directly with meals. The 1-yr and 5-yr survival rates were 73.7% and 55.8%, resp. Hepatic insufficiency directly related to alcoholic liver cirrhosis and/or its complications, including hepatic coma and acute anemia due to hemorrhage from the digestive tract, was the cause of 88% of all deaths.

7152 HIGH PREVALENCE OF HEPATITIS B VIRUS INFECTION AMONG HEAVY ALCOHOL DRINKERS IN JAPAN.

(Eng.) Naito, K.; Tsuji, T.; Nozaki, H.; Nagashima, H. (Okayama Univ. Medical Sch., 2-5-1 Shikata-cho, Okayama 700, Japan). *Microbiol. Immunol.* 21(12):735-738; 1978.

To clarify the pathogenesis of cirrhosis and chronic hepatitis in alcoholics, the prevalence of hepatitis B surface antigen (HBsAg), antibody to HBsAg (anti-HBs), and antibody to hepatitis B core antigen (anti-HBc) was examined in the sera of inhabitants of a district of Japan where alcohol drinking is popular and in controls. A group of 695 individuals from one city included 21 alcoholics (intake of >80 g ethanol/day for ≥5 yr), 421 nondrinkers, and 253 children (ages 3-12 yr). In addition, 675 individuals from a different city and 42,588 blood donors from this region were also studied. The frequency of HBsAg carriers did not differ significantly among these groups. The frequency of anti-HBs was 42.9% in the alcoholics, 21.1% in the nondrinkers, 5.1% in the children, 18.1% in the group from a different city, and 14.3% among 200 randomly selected blood donors from the larger group; the alcoholics differed significantly ($p<0.05$) from all the control groups. The alcoholics were 71.4% anti-HBc-positive, a rate significantly different ($p<0.05$) from the rates among the nondrinkers (43.0%), children (11.1%), or 200 blood donors (28.6%). The alcoholics also differed significantly ($p<0.05$) with respect to SGPT values. Alcoholics may be more accessible to hepatitis B virus (HBV), either through direct contact with infected individuals or because of impaired immunity. Alternatively, HBV may persist in minute quantities in the bodies of alcoholics, leading to increased antibody synthesis. It may also be that reinfection by HBV among alcoholics has a booster effect on antibody production. HBV appears to be closely related to the progression from alcoholic liver injury to cirrhosis.

7153 MITOCHONDRIAL ENZYME ACTIVITIES IN LIVER BIOPSIES FROM PATIENTS WITH ALCOHOLIC LIVER DISEASE.

(Eng.) Jenkins, W. J.; Peters, T. J. (Royal Postgraduate Medical Sch., London W12 OHS, England). *Gut* 19(5):341-344; 1978.

The hypothesis that mitochondrial damage is a significant factor in the pathogenesis of alcoholic liver disease (ALD) was investigated by enzymic analysis of mitochondrial fractions isolated from needle biopsy specimens from 13 control patients, 14 patients with fatty liver due to chronic alcoholism, and from 6 patients with other forms of liver disease. Enzymes associated with the inner and outer mitochondrial membranes (monoamine oxidase, succinic dehydrogenase, and cytochrome c oxidase) showed normal levels in ALD. Enzymes associated with the mitochondrial matrix (glutamate dehydrogenase, malate dehydrogenase, and aspartate aminotransferase) showed significantly raised levels in ALD compared with those in normal controls ($p<0.01$, $p<0.05$, and $p<0.02$, resp.), but the levels in patients with nonalcoholic liver disease were nor-al. In addition, analysis of the mitochondria by ucrose density gradient centrifugation revealed no ifferences between control tissue and liver from atients with alcoholic liver disease. These re- ults do not indicate that there is significant itochondrial damage in ALD. The raised levels of itochondrial matrix enzymes may represent an adap- ive response to the ethanol load.

154 STUDY OF PLASMA RENIN ACTIVITY DURING THE REINJECTION OF CONCENTRATED ASCITES IN IRRHOSIS [Abstract]. (Fre.) Hueber, D.; Levy, V. . (Hopital Saint-Antoine, Paris, France). *Gastro- nterol. Clin. Biol.* 1(8/9):712; 1977.

LIVER AND BILIARY TRACT

Cirrhosis

158 TESTOSTERONE IN THE MANAGEMENT OF CIRRHOSIS OF THE LIVER--A CONTROLLED STUDY. Eng.) Puliyel, M. M.; Vyas, G. P.; Mehta, G. S. Benziger Hosp., Quilon 691001, India). *Aust. N.Z.* . *Med.* 7(6):596-599; 1977.

 improve the treatment of cirrhosis of the iver, a controlled trial of testosterone therapy as carried out in 21 patients randomly assigned a control group (group I) and a testos- erone group (group II). Group I and group II re- eived frusemide (40 mg i.v. daily for 3 days and hen daily with KCl supplements); group II also eceived testosterone (100 mg parenterally on al- ernate days for 4 weeks, then 300 mg fortnightly). 11 31 patients had histologically confirmed portal irrhosis; in group I, 4 had postnecrotic cirrhosis nd 5 had nutritional cirrhosis; in group II, 6 atients each had postnecrotic or nutritional cir- hosis. At the end of 4 weeks, there was a minimum eduction of 2.5 cm in the size of the spleen and n average reduction of 2.5 kg in weight in group I, whereas in group I, average weight increased y 2.6 kg. Abdominal girth showed a mean decrease f 4.8 cm in group II and a mean increase of 4.7 m in group I. Total serum protein rose 8.8% in roup II but only 1.7% in group I; serum albumin ose 34.6% in group II but fell 12.5% in group I p<0.05); serum globulin fell 12.5% in group II but ose 14.7% in group I ($p<0.05$). The value of thymol turbidity showed some deterioration in group I patients but showed a significant ($p<0.01$) improvement in group II cases. An increased appetite was reported by 75% of group II patients but by only 11% of group I patients. No histologic changes were observed over the course of the study when initial and final needle biopsies were compared. The adverse side-effects were noted in patients of either sex. These results confirm those in other studies concerning the value of testosterone therapy for liver cirrhosis.

7159 PLASMAPERFUSION FOR THE TREATMENT OF INTRACTABLE PRURITUS OF CHOLESTASIS. (Eng.) Lauterburg, B. H.; Pineda, A. A.; Dickson, E. R.; Baldus, W. P.; Taswell, H. F. (Mayo Graduate Sch. Medicine, Rochester, MN). *Mayo Clin. Proc.* 53(5): 403-407; 1978.

The case of a patient with primary biliary cirrhosis and intractable pruritus who was treated with plasmaperfusion of charcoal-coated glass beads on two occasions is presented. The procedures were well tolerated and resulted in the removal of about 70% (494 µmol) of the estimated chenic acid pool. There was pronounced amelioration of the pruritus, which enabled the patient to sleep through the night without awakening because of itching. The pruritus, however, did not disappear and gradually returned to its preperfusion intensity by the end of the third week after perfusion. This case demonstrates that plasmaperfusion of charcoal-coated glass beads is a safe technique that effectively removes bile acids and bilirubin.

7160 ON THE POSSIBLE RELATIONSHIP BETWEEN PLASMA CEA AND THE SEVERITY OF CIRRHOSIS.

(Eng.) Mor, C.; Gamba, G.; Moro, E.; Gennari, L.; Orefice, S.; Rocco, P.; *et al.* (Ospedale "S. Marta," Rivolta d'Adda, CR, Italy). *Rend. Gastroenterol.* 9(2):118-121; 1977.

Two hundred eight patients with non-neoplastic liver diseases were studied to determine if there is a relationship between the presence of carcinoembryonic antigen (CEA) and various humoral indices characterizing liver diseases and to ascertain whether the frequency of positive results is correlated with the severity of the disease. Radioimmunoassay for CEA gave positive results in 6 of the 29 patients with steatosis, in 10 of the 27 with chronic hepatitis, in 30 of the 84 with cirrhosis, in 1 of the 57 with biliary lithiasis, and in 9 of the 11 with acute hepatitis. In the cirrhotic patients, there was a significant correlation ($0.05 < p < 0.01$) between CEA-positive sera and several abnormal hematochemical indices (albumin, α_2-globulin, γ-globulin, indirect bilirubin, direct bilirubin, and prothrombin activity levels). The results suggest that a positive CEA test in cirrhosis is directly related to the severity of the disease.

7161 ALTERATION OF HAEM SYNTHESIS IN CIRRHOSIS OF THE LIVER.

(Eng.) Kautzsch, E. (Medizinische Abteilung im Stadtischen Krankenhaus, Oberfohringerstr. 156, D-8000 Munchen-Oberfohring 81, W. Germany). *Acta Hepatogastroenterol. (Stuttg.)* 25(2):124-126; 1978.

To clarify disturbances of heme synthesis that occur in hepatic disorders, the levels of free protoporphyrins in RBC (EPP) were examined in 51 patients with liver cirrhosis (LC) and compared with values in 16 normal subjects, 14 patients with chronic fibrotic hepatitis (CFH), and 5 patients with chronic aggressive hepatitis. The LC patients fell into two groups. Group A (29 patients) had EPP values averaging close to the normal value (16.5 $\mu g/10^{11}$ RBC and 26.7 $\mu g/10^{11}$ RBC for group A and normals, resp.), whereas group B had markedly elevated EPP levels (44.2 $\mu g/10^{11}$ RBC) compared with normals. No relationship between EPP level and serum levels of SGOT, SGPT, bilirubin, iron, or protein was found in group A or B. The only consistent relationship was found between fat deposits in hepatocytes and EPP levels: a high level of one was always connected with a high level of the other. EPP levels in patients with CFH and CAH were 29.6 and 28.8 $\mu g/10^{11}$ RBC, resp. The increase in EPP level in LC may be due to a stimulating effect of a 5β-H-steroid metabolite on heme formation in the bone marrow or steroid metabolites involved in a feedback control mechanism may remain in the blood longer than is normal.

7162 IMMUNE COMPLEXES IN ACUTE AND CHRONIC LIVER DISEASE.

(Eng.) Thomas, H. C.; De Villiers, D.; Potter, B.; Hodgson, H.; Jain, S.; Jewell, D. P.; *et al.* (Royal Free Hosp., Pond St., Hampstead, London, England). *Clin. Exp. Immunol.* 31(2):150-157; 1978.

Sera from patients with acute type A and B viral hepatitis, paracetamol-induced necrosis, hepatitis B surface antigen (HBsAg)-positive and -negative chronic active and persistent hepatitis, various types of alcohol-induced liver injury, and primary biliary cirrhosis were examined for the presence of immune complexes, to investigate the possibility that the complexes found in HBsAg-negative chronic active hepatitis may result from liver damage and may also be present in other liver diseases. In acute type A hepatitis, a large increase in complement component Clq binding was demonstrated during the period of elevated levels of transaminases. In type B hepatitis, the initial peak was small but was followed by a further peak during the period of falling serum HBsAg. In both diseases, the Clq binding was associated with >20S particles. In paracetamol-induced necrosis, Clq binding remained normal. In type A and B hepatitis and in paracetamol-induced necrosis, C4, C3, and factor B concentrations were depressed in the early phase of the disease. This change may reflect either diminished synthesis or increased catabolism. In HBsAg-positive and -negative chronic active hepatitis and in alcohol-induced disease, there was a significant correlation between Clq binding and the severity of hepatitis. Clq binding and anticomplementary activity were also increased in primary biliary cirrhosis. Density gradient studies indicated that the Clq binding activity in these subjects lies in the 8-14S and >19S particle-containing fractions. These findings suggest the presence of immune complexes in patients with acute and chronic liver disease. In some cases, the complexes may contain hepatitis viral antigens, but in alcohol-induced and autoimmune disease, other types of complex formation must exist. The accumulation of large and small complexes in subjects with liver disease may be a reflection of an impaired function of the mononuclear phagocytes. The potential of these complexes to activate complement will determine their pathological importance, and in this respect, those found in primary biliary cirrhosis may have special significance.

7163 EVALUATION OF VOLATILE SULFUR COMPOUNDS IN THE EXPIRED ALVEOLAR GAS IN PATIENTS WITH LIVER CIRRHOSIS.

(Eng.) Kaji, H.; Hisamura, M.; Saito, N.; Murao, M. (Hokkaido Univ. Sch. Medicine, Nishi-7, Kita-15, Kita-ku, Sapporo 060, Japan). *Clin. Chim. Acta* 85(3):279-284; 1978.

To confirm the implication of methyl mercaptan and dimethyl sulfide reported in fetor hepaticus, fasting levels of these sulfur-containing compounds were determined by gas chromatography in the expired alveolar gas in 53 normal subjects, 13 patients with acute hepatitis, 11 patients with chronic hepatitis, 20 patients with liver cirrhosis, and 19 patients with stomach ulcer and/or undergoing gastric mucosal biopsy. The fasting level of dimethyl sulfide in the cirrhotics was 4.05 ± 1.06 ng/dl, which was a significant elevation in comparison with that in normal controls (1.54 ± 0.09 ng/dl, $p<0.05$). The dimethyl sulfide level in the cirrhotics was also significantly elevated in comparison with the levels in patients with acute hepatitis ($p<0.05$) and patients with ulcer and/or biopsy ($p<0.05$). In contrast, the methyl mercaptan levels were similar in all groups. Since there was no significant increase in sulfur-containing compounds in the patients with ulcer and/or biopsy, it appears that these compounds do not originate from gastrointestinal bleeding and are not produced by the activity of gastrointestinal microflora from sulfur-containing substrates. The physiological significance of these compounds in normal and pathologic states must be further studied.

7164 ABNORMAL VITAMIN D METABOLISM IN CIRRHOSIS.

(Eng.) Jung, R. T.; Davie, M.; unter, J. O.; Chalmers, T. M.; Lawson, D. E. M. Dunn Nutrition Lab. [MRC], Milton Rd., Cambridge, B4 1XJ, England). *Gut* 19(4):290-293; 1978.

o determine why low plasma 25-hydroxycholecalci- erol (25 OHD) values are found in liver cirrhosis, itamin D metabolism was investigated in 10 cir- hotic patients. The mean plasma 25 OHD concentra- ion in alcoholic cirrhosis was lower than that in ormal controls studied at the same time of year winter, 8.7 ± 3.99 versus 10.4 ± 3.8 ng/ml), but he difference was not significant. In three of our patients restudied in late summer, plasma 25 HD had risen. In contrast to the finding in normal ubjects, the half-life of i.v. administered ^{3}H- holecalciferol was short in cirrhotics and showed o correlation with plasma 25 OHD ($r=0.23$, $p=NS$), hereas half-life and plasma level of 25 OHD were orrelated in controls ($r=0.78$, $p<0.01$). Further- ore, the appearance of ^{3}H-25 OHD from ^{3}H-chole- alciferol was reduced compared to the control group hr after injection. An increased rate of chole- alciferol metabolism and deficient production of 5 OHD contribute to vitamin D deficiency in liver isease.

165 THE PORTAL TRIAD IN HEPATIC CIRRHOSIS.

(Eng.) Witte, C. L.; Witte, M. H.; mont, A. E. (Univ. Arizona Coll. Medicine, Tuc- on, AZ). *Surg. Gynecol. Obstet.* 146(6):965-974; 978.

o shed light on the triad of ascites, rupture of sophageal varices, and congestive splenomegaly in atients with cirrhosis, the origin and treatment this portal triad and its relation to portal ypertension are reviewed. Because critical events nfold in the relatively inaccessible hepatosplanchnic d, methodology has been a major stumbling block o obtaining detailed hemodynamic and lymphodynamic data. Direct measurement of organ blood flow usually is made under artificial or less than ideal conditions, for example, at laparotomy, quantitation of portasystemic collateral venous flow is indirect and at best a rough approximation; examination of lymph flow and composition in the thoracic duct and its major tributaries in the liver and extrahepatic portal bed is limited. However, a more comprehensive understanding of these phenomena is slowly emerging. Ascites begins with an imbalance of physiochemical forces at the capillary level in the liver and digestive tract. Large amounts of fluid are driven out of the vascular space into splanchnic tissues. When the rate of lymph return to the systemic venous circulation fails to keep pace with excessive capillary filtration, ascites appears. This situation leads to salt and water retention, involving the renin-aldosterone system. Plasma volume is restored, but at the same time hepatosplanchnic lymph formation is further enhanced, and a vicious circle is created. Treatment depends upon reduction of lymph formation by indirect, dietary restriction of salt and water and by diuretic drugs or by direct, portasystemic shunt, portal decompression or alternatively, upon acceleration of already rapid lymph return, by lymphvenous or peritoneovenous shunt, to match the high rate of lymph production. Spontaneous rupture of esophagogastric varices develops because of the precipitous rise in portal pressure when increased splanchnic blood flow combines with progressively rising portal vascular resistance. The greater the restriction to transhepatic portal venous flow, the less of an increment in splanchnic blood flow is required to generate pressures that ultimately exceed the bursting tension of thin-walled varices. Treatment is based on attempts to lower resistance to esophagogastric venous flow. Splenomegaly in patients with liver disease primarily derives from hepatocellular dysfunction with compensatory reticuloendothelial hyperactivity in the congested spleen. Splenic arterial flow increases as the demand for blood flow rises from splenic work hypertrophy, and peripheral cytopenias may develop. Treatment of symptomatic hypersplenism requires reduction of splenic mass either by restricting splenic arterial inflow or ablating the spleen.

7166 MANAGEMENT OF HEPATIC ASCITES.

(Eng.) Anonymous. (No affiliation given). *Lancet* 1(8059):311-312; 1978.

The management of hepatic ascites is reviewed. Reduction of serum colloid osmotic pressure (related to defective hepatic albumin synthesis) combined with portal hypertension due to obstruction are the principal causes. Intrasinusoidal pressure rises and causes hepatic lymph overproduction, and the kidney attempts to compensate for fluid loss into the peritoneum by conserving water and sodium. Basic treatment is restriction of dietary sodium and fluid intake together with a combination of sodium-losing and potassium-conserving diuretics. Over-diuresis is a danger, particularly potassium depletion and hepatic encephalopathy; diuresis-refractory patients may develop hepatorenal syndrome (functional renal failure). Large abdominal paracenteses are contraindicated except for diagnosis and urgent relief of painful, tense ascites. Reinfusion, either of unaltered ascitic fluid or of ultrafiltered fluid may bring relief in nonmalignant cases. A peritoneo-venous shunt has been developed that drains the peritoneal cavity via a tube into the internal or external jugular vein, using respiration as the force to open and shut a valve in the system. This technique may be particularly useful in Budd-Chiari syndrome; the exact mortality and morbidity are not yet clear. Long-term trials comparing all these methods are urgently needed.

7167 CUTANEOUS GRANULOMATA WITH PRIMARY BILIARY CIRRHOSIS. (Eng.) Byrne, J. P. H.; Cochrane, A. M. G.; Williams, D. I.; Williams, R. (King's Coll. Hosp. and Medical Sch., Denmark Hill, London SE5 9RS, England). *Proc. R. Soc. Med.* 70(12):897-898; 1977.

The case of a patient with primary biliary cirrhosis who presented with cutaneous granulomata is reported. The patient, a 74-yr-old woman, had a 2-yr history of generalized pruritus that was associated for the last year with a widespread sheeted papular eruption in the trunk and limbs. On examination, there was slight generalized hyperpigmentation and a sheeted glistening flesh-colored papular eruption affecting the upper chest, back, and arms. A skin biopsy revealed granulomata in the dermis consisting of monuclear cells, epithelioid cells, and Langhan's type giant cells. A liver biopsy showed changes consistent with primary biliary cirrhosis. The patient was treated with cholestyramine, methyl cellulose eye drops, and monthly injections of vitamins A, D, and K. The authors hypothesize that circulating complexes involving IgM, which is elevated in primary biliary cirrhosis, lodge in the skin causing a vasculitis with subsequent granulomatous formation.

7168 HYPERGLUCAGONEMIA IN CIRRHOSIS: ALTERED SECRETION AND SENSITIVITY TO GLUCAGON. (Eng.) Sherwin, R. S.; Fisher, M.; Bessoff, J.; Snyder, N.; Hendler, R.; Conn, H. O.; Felig, P. (Yale Univ. Sch. Medicine, New Haven, CT 06510). *Gastroenterology* 74(6):1224-1228; 1978.

To study the mechanism of hyperglucagonemia in liver cirrhosis, the turnover of plasma glucagon was examined in cirrhosis. In addition, the effect of cirrhosis on tissue responsiveness to physiological increments in plasma glucagon was studied. The plasma glucagon concentration was elevated two- to sixfold in 13 cirrhotic patients with spontaneous portal systemic shunting or surgically induced portacaval anastomosis, but it was comparable to that in the 15 controls in the 4 cirrhotics without portasystemic shunting. The metabolic clearance rate of glucagon was normal in all of the cirrhotic groups, but the estimated basal systemic delivery rate of glucagon was increased two- to sixfold in the hyperglucagonemic patients. The blood glucose response to infusion of glucagon (3 ng/kg/min) was reduced in the cirrhotics with portasystemic shunting or portacaval anastomosis ($p<0.05$), and correlated inversely with the delivery rate of endogenous glucagon ($r=0.63$, $p<0.01$). The administra- tion of ammonium chloride (3 g) failed to elevate plasma glucagon concentration. It is concluded that hyperglucagonemia in cirrhosis is a consequence of hypersecretion rather than decreased hormonal catabolism. A negative feedback signal may exist between hepatic sensitivity to glucagon and the secretion of this hormone.

7169 MYELOPATHY IN CIRRHOSIS. (Eng.) Robinson, C. E.; Anzarut, A. (G. F. Strong Rehabilitation Center, Canada). *Paraplegia* 16(1):3-4; 1978.

The case of a patient with spinal cord disease associated with portacaval shunt for portal hypertension and cirrhosis is presented. Several months after the shunt was performed, the patient began to complain of weakness in the extremities, especially in the legs. When he was hospitalized 1 yr later, he had difficulty walking due to a spastic gait. He also had clinical jaundice, hepatomegaly, and some pedal edema. He had continued to drink excessively following surgery. He was found to have spastic tetraparesis but no sensory impairment. Bilateral adductor tenotomies were done to improve the patient's gait. Despite lower extremity weakness and spasticity, he was able to walk in parallel bars or with a walker, wearing below-knee braces. However, his rehabilitation program was interrupted on several occasions by dietary protein excess and hepatic precoma. The authors feel that he will not be a functional walker and will depend on a wheelchair for locomotion.

7170 EVIDENCE THAT ANGIOTENSIN-II PLAYS AN IMPORTANT ROLE IN THE HOMEOSTASIS OF ARTERIAL PRESSURE IN CIRRHOSIS WITH ASCITES [Abstract]. (Eng.) Arroyo, V.; Bosch, J.; Navarro, F.; Betriu, A.; Mauri, M.; Rodes, J. (Hospital Clinico y Provincial, Barcelona, Spain). *Digestion* 16(4):350-351; 1977.

Gallbladder and Biliary Tract Diseases

173 POSTOPERATIVE BIOPSY OF THE COMMON BILE DUCT VIA THE T-TUBE TRACT. (Eng.) Pala-ew, M. J.; Stein, L. (McGill Univ. and Jewish Gen-ral Hosp., 3755 Cote St. Catherine Rd., Montreal, uebec H3T 1E2, Canada). *Am. J. Roentgenol.* 130(2): 37-289; 1978.

o cases of postoperative common bile duct forceps iopsy via a postoperative T-tube tract are present-d. Both patients underwent this procedure because f fixed postoperative filling defects in the common ile duct. Using this technique, a neoplastic pro-ess could be excluded in both cases. Although the rocedure was well tolerated without incident or mplication in both patients, bleeding, perfora-ion, and pancreatitis could occur if caution is not ployed.

74 ENDOSCOPIC RETROGRADE CHOLANGIOPANCREATOGRAPHY IN A SURGICAL UNIT. (Eng.) Stan-rtskjold-Nordenstam, C. G.; Fraki, O. I. (Univ. ntral Hosp., SF-00290 Helsinki 29, Finland). *n. Clin. Res.* 10(1):30-37; 1978.

e value of endoscopic retrograde cholangiopancre-ography (ERCP) in the diagnosis of biliary and ncreatic diseases was assessed by reviewing the sults of 200 procedures performed on 195 patients a surgical unit. ERCP was diagnostic in 80% of e cases. The indications for the procedure were undice (27%), postcholecystectomy pain (22%), recur-nt acute pancreatitis (19%), complicated attack acute pancreatitis (14%), and other (18%). The sults of endoscopic retrograde cholangiography re normal in 26% of patients with persistent undice, and operation was thus avoided. In pa-ents with postcholecystectomy pain, pathological ndings were found in 50%, and half of them were erated upon. In pancreatitis, demonstration of e pancreatic ducts and grading of the disease cilitated selection of the treatment and enabled eoperative planning of the surgical procedure. e pancreas was resected in 13 of 59 cases with agnostic endoscopic retrograde pancreatography. pancreatic carcinoma, ERCP led directly to agnosis, but only 2 (ampullary carcinomas) of 10 re operable. The overall complication rate was , including one case of fatal hemorrhagic pan-eatitis.

75 EFFECT OF CALCITONIN ON THE SERUM AMYLASE LEVELS AFTER ENDOSCOPIC RETROGRADE CHO-NGIOPANCREATOGRAPHY. (Eng.) Odes, H. S.; Novis, N.; Barbezat, G. O.; Bank, S. (Groote Schuur sp., Observatory, 7925 Cape Town, South Africa). *gestion* 16(1/2):180-184; 1977.

ouble-blind study of the effect of calcitonin carried out in 30 patients undergoing endoscopic rograde cholangiopancreatography (ERCP), to de-mine whether calcitonin might protect against pancreatitis and hyperamylasemia, which sometimes complicate this procedure. Seventeen patients received an i.v. calcitonin infusion (2.5 μg/hr diluted in 50 ml 0.154 M NaCl) and 13 received a control NaCl infusion 4 hr before ERCP. There was no significant difference in the mean serum amylase concentration in patients receiving calcitonin or placebo during any of five observation periods. Five patients on calcitonin had abnormally high serum amylase levels, and two of the five developed abdominal pain typical of acute pancreatitis. Among those who received placebo, two had high serum amylase levels and abdominal pain. There was no significant difference in the urinary amylase output after ERCP in patients receiving calcitonin or placebo. The results suggest that calcitonin does not reduce the incidence of hyperamylasemia or pancreatitis after ERCP.

7176 RISK OF CANNULATION OF THE PAPILLA OF VATER. (Eng.) Myren, J. (No affiliation given). *Scand. J. Gastroenterol.* 12(Suppl. 47):22-24; 1977.

A review of complications following endoscopic retrograde cholangiopancreaticography (ERCP) is presented using several large series recently reported. In a series of 8,691 cases in the United States, the success rate was 70%, frequency of complications about 3%, and death as a consequence of complications 0.2%. Pancreatitis after injection was found in 1% of cases; there were no deaths in this series. Pancreatic sepsis was observed in 25 cases, most probably caused by injection of the contrast medium into pseudocysts or behind stenoses; 5 of these patients died. Cholangitis was observed in 0.8% of cases and 8 of these 72 patients died, with 90% of them having obstructed bile ducts; prompt surgical intervention in such cases is important. Instrumental injury occurred in 16 patients, duodenal perforation in 3 with 1 death, and bleeding from esophageal varices in 1 patient with 1 death. Abnormal anatomy of the stomach and duodenum is a common cause of these complications, which may be prevented by prior x-ray examination. Among 12,421 patients in Europe and Japan, endoscopic retrograde cholangiography (ERC) was performed in 8,060 cases and endoscopic retrograde pancreaticography (ERP) in 10,004 cases. Cholangitis occurred in 0.38% and 0.65% of the ERC and ERP procedures, resp., and pancreatitis occurred only after ERP (0.65%, 9 of the 65 patients died). ERCP is a valuable method in which benefit far exceeds the risk.

7177 BILE DUCT ADENOMAS AS LIVER NODULES. (Eng.) Cho, C.; Rullis, I.; Rogers, L. S. (Veterans Admin. Hosp., Syracuse, NY 13210). *Arch. Surg.* 113(3):272-274; 1978.

To improve the differential diagnosis of bile duct adenoma or benign cholangioma from metastatic tumor, two case reports and 2,125 consecutive autopsy cases from a 10-yr period were reviewed. A 59-yr-old man with ulcerative colitis was suspected of having a malignancy on x-ray examination of the sigmoid colon. A frozen section biopsy was thought to reveal a metastatic well-differentiated adenocarcinoma, but re-examination of the permanent stained section established the diagnosis of bile duct adenoma. A 48-yr-old man injured in a car accident was found to have a single, whitish, 0.5-cm, firm nodule in the right lobe of the liver; it was diagnosed by frozen section as bile duct adenoma. Among the biopsy cases, 0.6% were found to have had bile duct adenomas; each case was an incidental finding, the clinical records showed no symptoms or signs related to the lesions, and the cause of death was not related to the adenomas in any case. A single nodule was found in nine cases, two nodules in three cases, and multiple lesions in one case; all were <1.0 cm in diameter; they were grayish-white to slightly yellow, subcapsular nodules and fell histologically into three groups. Group 1, bile duct adenoma with active bile duct proliferation and considerable lymphocytic infiltrate, included lesions relatively well-demarcated from surrounding liver tissue that showed irregularly branching and proliferating bile ducts with cuboidal, pale acidophilic to basophilic epithelial linings; the stroma was invariably infiltrated by lymphocytes and there were occasional lymphoid aggregates either in the nodule or at the periphery. The uniformity of cells and lack of atypia generally warrant diagnosis as a benign lesion, but, as in the first case, it can be mistaken for metastatic malignancy. Group 2, bile duct adenoma with abundant hyalinized stroma and sparse, inactive bile ducts, were generally well-demarcated, nonencapsulated, wedge-shaped lesions with a wide base on the capsular surface. Stroma was abundant with collagenation widely separating tubular lumens lined by flattened epithelium. Normal portal triads were generally difficult to identify and there were occasional lymphocytic infiltrates. Group 3, multiple bile duct adenomatosis, included lesions similar morphologically to those in group 2. There were numerous lesions in the parenchyma and a few subcapsularly, some interconnecting each other. Occasionally the bile ducts were greatly dilated to form cystic spaces, which could contain acidophilic proteinaceous material or bile.

7178 STUDIES ON THE PATHOGENESIS OF BILIARY ATRESIA.

(Eng.) Witzleben, C. L.; Buck, B. E.; Schnaufer, L.; Brzosko, W. J. (Children's Hosp. Philadelphia, 34th St. and Civic Center Blvd., Philadelphia, PA 19104). *Lab. Invest.* 38(5):525-532; 1978.

Liver biopsy and the extrahepatic biliary system from five infants (age 6 weeks-2.5 months) who underwent portoenterostomy for biliary atresia were studied by light microscopy to delineate the character and distribution of the anatomic lesions and by culture and immunofluorescence techniques for evidence of two viruses (cytomegalovirus and hepatitis B) that have been suspected in the genesis of biliary atresia. The case reports of the patients are presented. Control preparations were obtained from age-matched controls. The liver biopsies showed typical findings, with variable giant cell transformation, cholestasis, and prominent bile duct proliferation. In the extrahepatic biliary system, in all five cases there was lumen obliteration in the common hepatic duct, and in three cases there was also comparable obliteration in the common bile duct. No lumen dilation was evident proximal to the areas of obliteration. In the areas of obliteration, there was evidence of a resolving inflammatory process. Where the lumen was present, it tended to be small, especially in the hepatic and common ducts. In the porta hepatis, there appeared to be various stages of an evolving lesion, the earliest stage of which included extensive active epithelial injury with developing fibrosis, and the latest, more advanced fibrosis with reduction in duct lumen area. In the earlier stage, a dense inflammatory infiltrate, with small numbers of polymorphonuclear leukocytes, numerous lymphocytes, plasma cells, and eosinophils, was present. In the latter stage, mononuclear cells predominated, polymorphonuclear leukocytes were scant, but eosinophils were often still quite prominent. These findings demonstrate the presence of active ductal epithelial injury, at least in the porta hepatis, in this age group. There was no evidence of cytomegalovirus in any case or of hepatitis B in three of five cases. In two cases, one of the less specific techniques showed suggestive evidence of hepatitis B in the liver. These latter findings suggest that other viruses need to be sought or that cases should be studied at an earlier stage for the presence of these viruses.

7179 EXTRAHEPATIC BILIARY ATRESIA: RECENT DEVELOPMENTS IN MANAGEMENT.

(Eng.) Howard, E. R.; Mowat, A. P. (King's Coll. Hosp. Medical Sch., London SE5 8RX, England). *Arch. Dis. Child.* 52(11):825-827; 1977.

Developments in the management of extrahepatic biliary atresia in infants are briefly reviewed. Extrahepatic biliary atresia is commonly divided into surgically correctable and noncorrectable types. The former, accounting for approximately 15% of all cases, implies that there is a segment of extrahepatic bile duct, patent up to the porta hepatis, available for direct biliary-intestinal anastomosis no such segment is present in the noncorrectable cases. Although a satisfactory anastomosis may be created between bile duct and bowel in the "correctable" cases, only a minority of patients drain bile satisfactorily and survive for an extended period. Attempts to treat the "noncorrectable" types by partial hepatic resection, insertion of drainage tubes in the hepatic parenchyma, thoracic duct drainage to the esophagus, and hepatic lymph drainage to the jejunum have all failed. One author has shown that removal of the extrahepatic bile ducts and anastomosis of a loop of bowel to the area of the porta hepatis could result in bile drainage and long-term survival. Efforts to replicate this author's work were not universally successful, but the most recent reports from his unit suggest that if the operation is carried out

60 days of age, 80% will develop bile drainage, lling to 20% if delayed beyond this point. Three mplications commonly occur after portoenteros- my: recurrent cholangitis, increased intrahepatic brosis, and portal hypertension. The introduction portoenterostomy has clearly increased the ances of long-term survival in infants with ex- nsive destruction of the extrahepatic bile ducts, t such survival is still only achieved in a min- ity of patients. It appears that previous advice postpone surgery in cases of suspected biliary resia is not in the best interest of the patient.

30 EXPERIMENTAL INVESTIGATIONS INTO THE ETIOLOGY OF CHOLANGITIS FOLLOWING OPERA- N FOR BILIARY ATRESIA.

(Eng.) Hirsig, J.; a, O.; Rickham, P. P. (Dept. Pediatric Surgery, v. Zurich, Zurich, Switzerland). *J. Pediatr. g.* 13(1):55-57; 1978.

eriments were carried out on 8-week-old Gottingen ipigs to investigate the causation of cholang- s seen after hepato-porto-entero anastomosis. group 1 (7 animals), the bile duct was ligated the gallbladder was excised. In group 2 (5 mals), the lymphatic drainage of the liver was troyed by resecting and ligating all lymphatic sels in the region of the porta hepatis and by ision of the periportal lymph glands. In group 3 animals), the bile duct was tied and the lympha- drainage was resected. In group 4 (7 animals), bile duct was ligated, and bilateral truncal otomy was performed. In group 5 (22 animals), the rations performed in group 3 were repeated, and ateral truncal vagotomy was added. The incidence cholangitis was 0/7, 0/7, and 0/5 in groups 1, 2, 4, resp.; the incidence of cholangitis with atic abscesses was 5/7 and 13/22 in groups 3 5, resp. It appears that, in the minipig, the ces of postoperative cholangitis are much in- ised if the lymphatic drainage from the liver t least partially destroyed. *Streptococcus dans, S. hemolyticus*, and *Staphylococcus aureus* often found, and *Escherichia coli* and *Kleb- la* were occasionally discovered. These in- ions were found only in the liver and were ably hematogenous in origin, brought about by rfering with the resistance of the hepatic culoendothelial system by destroying the lym- ic drainage. Recent clinical experience is cited to support the conclusion that when a tic portoenterostomy is carried out for biliary sia, trauma to the lymphatics in the porta tis should be avoided, and an additional omento- to-portopexy should be done.

RECURRENT PYOGENIC CHOLANGITIS: A STUDY BY ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY.

.) Lam, S. K.; Wong, K. P.; Chan, P. K. W.; , H.; Ong, G. B. (Queen Mary Hosp., Hong Kong). *roenterology* 74(6):1196-1203; 1978.

applicability and clinical value of endoscopic ograde cholangiograms were studied in 52 patients recurrent pyogenic cholangitis. The earlier changes of recurrent pyogenic cholangitis were identified and found to be confined to the intrahepatic biliary tree. The left hepatic duct was more severely affected than the right hepatic duct and had a higher infestation by clonorchis. The severity of radiological changes correlated well with the duration of illness and the need for surgery. Gallstones were present in 34.2% of the patients and pancreatic ductal abnormality in 7.7%. The decision for surgery could be made early and accurately, and the type of surgery and the assignment of surgeons could be planned in advance. Cholangitis complicated endoscopic retrograde cholangiograms in 23.1% of the initial 26 patients without antibiotic cover but in none of the subsequent 26 in whom this was used. This study shows that endoscopic retrograde cholangiography confers significant advantages to the management of recurrent pyogenic cholangitis.

7182 A FATHER AND SON WITH CHOLESTASIS AND PERIPHERAL PULMONIC STENOSIS.

(Eng.) Riley, C. A.; LaBrecque, D. R.; Ghent, C.; Horwich, A.; Klatskin, G. (Yale Univ. Sch. Medicine, 333 Cedar St., New Haven, CT 06510). *J. Pediatr.* 92(3): 406-411; 1978.

The case reports of a 27-yr-old man and his infant son are presented to establish diagnostic criteria for the syndrome of cholestasis and peripheral pulmonic stenosis (PPS) that permit its differentiation from Byler disease, a progressive form of intrahepatic cholestasis. Both the father and son presented with neonatal jaundice and cardiovascular abnormalities, have frontal bossing, vertebral anomalies, hypercholesterolemia, and mild malabsorption of fat. Early liver biopsy reveals the absence of the bile ducts; late liver biopsy shows no cirrhosis or fibrosis. Survival is prolonged. The syndrome appears to be inherited as an autosomal dominant trait. In Byler disease, the presenting symptom is malabsorption; jaundice occurs in attacks and then persists; cholesterol level is normal or low; there is rickets and no cardiovascular malformation; early liver biopsy shows fibrosis or decreased ducts; late biopsy shows cirrhosis; death occurs in childhood; and the trait behaves as an autosomal recessive. The most likely underlying pathogenesis of cholestasis with PPS is an inborn error of metabolism. It is postulated that there may be a defect in bile formation, perhaps a defect in bile acid or cholesterol excretion, resulting in a diminution of total bile flow that causes a rapidly progressive atrophy of a majority of the intrahepatic bile ducts shortly after birth. Choledochoduodenostomy has been used as therapy, but with unclear benefit. Cholestyramine and phenobarbital were not of benefit to the father. There are other aspects of these cases that remain unclear and warrant additional investigation.

7183 I^{131}-ROSE BENGAL SCANNING IN THE DETECTION OF CHOLECYSTOCOLIC FISTULA: NEW USE OF AN ESTABLISHED PROCEDURE.

(Eng.) Zaw-Win, B.; Darwish, M.; Dibos, P. E.; Razzak, I. A. (Franklin Square Hosp., Towson, MD). *Am. J. Gastroenterol.* 68(4):396-398; 1978.

The case of a 60-yr-old man who was admitted to hospital with a 3-month weight loss of 12.5 kg and vague right upper quadrant pain is presented. Previous examination had revealed chronic gastritis and abnormal liver function tests. Upper gastrointestinal series, barium enema, abdominal sonography, and celiac angiogram failed to reveal an abnormality. The gallbladder was not visualized on a p.o. cholangiogram or an i.v. cholangiogram, but air was seen in the biliary tree. A ^{131}I-rose bengal liver study revealed normal distribution of the tracer in the liver 30 min after injection, normal activity in the liver, gallbladder, transverse colon, and splenic flexure at 2 hr, and decreasing activity in the liver with increasing activity in the transverse colon and splenic flexure after 4 hr. These findings suggested a cholecystocolic fistula, which was confirmed at laparotomy. Cholecystectomy and repair of the cholecystocolic fistula were performed. Pathological examination revealed chronic cholecystitis and cholelithiasis. It is recommended that ^{131}I-rose bengal studies be used in patients suspected of having fistulas between the gallbladder and other organs. The procedure is relatively simple, safe, and noninvasive; its diagnostic sensitivity remains to be established.

7184 HEPATIC FUNCTION IN CHOLELITHIASIS. (Pol.)

Markert, R. (Instytut Chirurgii AM, ul. Zelwerowicza 26a, 90-147 Lodz, Poland). *Pol. Przegl. Chir.* 49(12):1265-1270; 1977.

Liver function tests were performed in 50 patients with uncomplicated cholelithiasis before, immediately and 6-12 months after surgery. Liver tissue samples collected during surgery were also examined histologically; they showed chronic hepatitis in 30% of the patients. The BSP retention was increased in all patients before, immediately after, and 6-12 months after surgery; increases of >20% were found in 36% of the patients before surgery, in 18% immediately after surgery, and in 12% 6-12 months after surgery. The aspartate-aminotransferase activity was increased in 28% of the patients before surgery, in 20% after surgery, and in 2% 6-12 months after surgery. The alanine-aminotransferase activity was increased in 43% of the patients before surgery, in 38% after surgery, and in 9% 6-12 months after surgery. Symptoms of impaired hepatic function persisted in 10% of the patients. The findings indicate that surgery does not always lead to full recovery.

7185 PRESENT FEATURES OF GALLSTONES IN JAPAN: A COLLECTIVE REVIEW OF 2,144 CASES. (Eng.)

Nagase, M.; Tanimura, H.; Setoyama, M.; Hikasa, Y. (Kyoto Univ. Sch. Medicine, Shogoin, Sakyoku, Kyoto, Japan 606). *Am. J. Surg.* 135(6):788-790; 1978.

The types and sites of gallstones were studied in 2,144 patients operated on for cholelithiasis at 37 hospitals during the last 22 months. Cholesterol stones were seen in 70.4% of patients, and 86.3% of the cholesterol stones occurred in the gallbladder alone. Bilirubin stones were seen in 23.5% of cases and were almost equally distributed in the gallbladder and the common bile duct. Most patients younger than 39 yr had cholesterol gallstones, and these were located mainly in the gallbladder. In contrast, patients older than 60 yr mostly had bilirubin stones, and these were located in both the common bile duct and the gallbladder. Almost twice as many women as men had cholesterol stones, but no sex difference was noted with bilirubin stones. The authors conclude that recent westernization of dietary habits in Japan is the most probable factor causing the increased incidence of cholesterol gallstones. The decreased incidence of bilirubin stone may be caused by the decreased incidence of biliary infection and increased intake of dietary protein.

7186 COMPARISON BETWEEN THE USE OF ORAL CONTRACEPTIVES AND THE INCIDENCE OF SURGICALLY CONFIRMED GALLSTONE DISEASE. (Eng.)

Leissner, K. H.; Wedel, H.; Schersten, T. (Sahlgrenska sjukhuset, S-413 45, Goteborg, Sweden). *Scand. J. Gastroenterol.* 12(7):893-896; 1977.

To determine whether there is a relationship between the use of oral contraceptives and the development of gallstone disease, the incidences of gallstone surgery in women and men in two Swedish cities in 1961 (before the introduction of oral contraceptives) were investigated and compared with the corresponding incidences in 1971 (2 yr after the peak sale of oral contraceptives and 6 yr after their introduction). The number of cholecystectomies in men in both cities increased from 222 pe 1,000 inhabitants in 1961 to 406/1,000 in 1971 and women from 384/1,000 to 597/1,000. In one city (Falun), there was an increased incidence of cholecystectomies in women aged 25-29 yr and those aged 55-65 yr between 1961 and 1971. The change in the incidence of cholecystectomy in men and women in Gothenburg was statistically analyzed, using the ratio $(f^a_{71}/f^a_{61})/(m^a_{71}/m^a_{61})$, in which f^a_{61} and f^a_{71} denote the incidence for women in any 5-yr age gro for 1961 and 1971 and m^a_{61} and m^a_{71} denote the corresponding incidences for men. The ratio was above unity in the ages between 25 and 54 yr and reached statistical significance in the age groups 25-29, 35-39, and 40-44 yr (p=0.029, p=0.024, and p=0.045, resp.). These findings suggest a causal relationship between the use of oral contraceptive and the development of gallstones.

7187 A PROSPECTIVE STUDY OF THE CLINICAL VALU AND ACCURACY OF GREY SCALE ULTRASOUND I DETECTING GALLSTONES. (Eng.)

McKay, A. J.; Dunca J. G.; Imrie, C. W.; Joffe, S. N.; Blumgart, L. H. (Royal Infirmary, Glasgow, Scotland). *Br. J. Surg* 65(5):330-333; 1978.

The accuracy and possible clinical value of grey scale ultrasonography in the detection of gallstones were studied prospectively in 100 unselecte patients presenting with recurrent biliary colic, acute cholecystitis, or acute pancreatitis. Adequate visualization of the gallbladder was obtain

in 79 cases, with 3 false-positive and no false-
egative results. In patients in whom scanning
as technically satisfactory and adequate visuali-
ation was obtained, the presence or absence of
allstones was correctly diagnosed in 96%. The
allbladder was adequately visualized in 80% of
0 patients with recurrent biliary colic, in 87%
f 30 patients with acute cholecystitis, and 73%
f 40 patients with acute pancreatitis. One of
he false-positive results occurred in the biliary
olic group. This patient showed several discrete
roups of echoes on the posterior wall without
hadowing. The other two false-positive cases
ere recorded in the acute pancreatitis group;
either demonstrated shadowing, but both showed
n irregular area of increased echoes along a seg-
ent of the posterior wall of the gallbladder. The
ajor cause of failure was the presence of intes-
inal gas obscuring the ultrasound image, and the
allbladder was not visualized in 21% of the cases.
rey scale ultrasonography is of value in patients
n whom oral cholecystography fails or is contra-
ndicated and in patients with compromised liver
nction.

188 COMPARISON OF FIXED DOSES OF CHENODEOXYCHOLIC ACID FOR GALLSTONE DISSOLUTION.

Eng.) Bateson, M. C.; Murison, J.; Ross, P. E.;
ouchier, I. A. D. (Ninewells Hosp. and Medical
ch., Dundee DD1 9SY, Scotland). *Lancet* 1(8074):
11-1114; 1978.

nety-six patients with gallstones who were treated
r up to 4 yr with chenodeoxycholic acid in daily
ses of 500, 750, or 1,000 mg were studied to de-
rmine whether fixed-dose therapy can be used suc-
ssfully in clinical practice and to establish
ether there are any differences in response to
fferent doses. None of the patients started on
0 mg daily showed complete gallstone dissolution.
ght of 41 patients on 750 mg daily had complete
ssolution of their radiolucent gallbladder stones
ter 6 or more months, and a further 4 showed
rtial dissolution. Five of 28 patients on 1,000
daily had complete dissolution of their radio-
cent stones after at least 6 months, and a further
showed partial gallstone dissolution. The mean
ration of therapy was greater on 750 mg than on
000 mg/day (1.27 versus 0.58 yr), and when results
re analyzed after the first 6 months of therapy,
e total response-rate was significantly ($p<0.05$)
eater for the 1,000 mg dose (13/28) than for the
0 mg dose (9/41). The individual response of
diolucent gallbladder stones to therapy could not
predicted from stone size, weight of patient,
sage per kg, or change in biliary lipids. Treat-
nt of radiolucent gallstones with chenodeoxycholic
id should start at 1,000 mg daily.

89 SUCCESSFUL REMOVAL OF RETAINED BILE DUCT STONES BY ENDOSCOPIC SPHINCTEROTOMY.

g.) Byrnes, D. J.; Hennessy, W. B.; Meredith,
G.; Piper, R. B. (St. Vincent's Hosp., Sydney,
South Wales 2010, Australia). *Med. J. Aust.*
4):803-804: 1977.

Two cases in which endoscopic sphincterotomy was successful in allowing the passage of stones retained in the common bile duct after cholecystectomy are presented. In the first patient, a 55-yr-old woman who had experienced four episodes of jaundice during a 14-yr period following cholecystectomy, an i.v. cholangiogram failed to outline the common bile duct. Endoscopic retrograde cholangiography showed the common duct to be grossly dilated and to contain five calculi, each approximately 1 cm in diameter. A 1.5-cm sphincterotomy was performed; this procedure was followed by a gush of bile and dye into the duodenum. During the following week, the patient experienced an episode of epigastric pain, and a second endoscopic cholangiogram confirmed that all calculi had been passed. In the second patient, a 29-yr-old woman, a post-cholecystectomy T-tube cholangiogram revealed two calculi in the common bile duct. Endoscopic sphincterotomy was performed 3 weeks after the operation. The T-tube was then flushed with sterile saline under antibiotic cover. The infusion was suspended after the patient had a rigor 12 hr later. A second T-tube cholangiogram showed that one stone remained. The sphincterotomy was extended, and this was followed by passage of the second stone. In this case, the authors feel that the surgeon's being able to perfuse the bile duct through the T-tube may have been a factor in ensuring passage of the stones.

7190 OPERATIVE CHOLANGIOGRAPHY IN TWO HUNDRED CONSECUTIVE CHOLECYSTECTOMIES. (Eng.)

Sugrue, W. J.; Stewart, R. J.; Pascoe, D. L.; Macbeth, W. A. A. G. (Christchurch Clinical Sch. Medicine, Christchurch, New Zealand). *N.Z. Med. J.* 86(600):470-471; 1977.

The value of operative cholangiography and the reasons for its failure were assessed by reviewing the records of 200 consecutive patients undergoing cholecystectomy for gallstones. Of these, 164 had an operative cholangiogram; the remaining 36 had no examination because of satisfactory preoperative x-rays of the bile ducts, inability to cannulate the cystic duct, x-ray machine failure, anticipated hazard to the patient, emergency cholecystectomy, no arrangements made, and easily palpable common bile duct stones. There were 37 patients who had one or more traditional criteria for common bile duct exploration but had a normal cholangiogram; these patients were thus spared unnecessary choledochotomy. Unsuspected common duct stones were detected by cholangiography in three patients. In 31 examinations that were considered to be failures, the major faults were exposure or film fault in 9, incorrect tube positioning in 9, nonvisualization of hepatic ducts in 6, obscuring of the bile ducts by the spine in 4, and catheter tip in duodenum in 3. It appears that the major advantage of operative cholangiography lies in the avoidance of unnecessary common bile duct exploration.

7191 THE REASONS FOR FAILURE OF ENDOSCOPIC RETROGRADE CHOLANGIO-PANCREATOGRAPHY IN

PATIENTS WITH JAUNDICE. (Eng.) Hoare, A. M.; West, R. J.; Cockel, R. (Queen Elizabeth Hosp., Birmingham 15, England). *Clin. Radiol.* 29(2):201-203; 1978.

The results of 100 consecutive attempts by experienced endoscopists at endoscopic retrograde cholangiopancreatography (ERCP) in jaundiced patients were analyzed to determine the cause for failure. The indications for endoscopy were cholestasis in 74 patients and liver function tests suggestive of incomplete biliary obstruction in 26 (12 of whom had previously undergone cholecystectomy). ERCP provided a diagnosis in 75/100 of the cases. The reason for failure to cannulate the correct duct was obstruction at the lower end of the common bile duct in 15 patients, distortion of the duodenum in 7, and broken instrument in 1; there was no cause for failure in the remaining 2 cases (both had intrahepatic cholestasis and tolerated the procedure poorly). Failure due to obstruction was caused most frequently by carcinoma of the pancreas (8 cases) or by a stone in the common bile duct (5 cases). It is difficult to see how increased skill could have made cannulation succeed in most of these 25 patients. Transhepatic cholangiography may be a possible alternative method of diagnosis in such cases.

7192 ULTRASONIC EXAMINATION IN JAUNDICE. (Ger.) Rettenmaier, G.; Seitz, K. H. (Innere Abteilung des Kreiskrankenhauses, Bunsenstr. 120, 7030 Boblingen, W. Germany). *Dtsch. Med. Wochenschr.* 102(43):1559-1560; 1977.

Experience with the sonographic diagnosis of jaundice is reported. Sonography makes it possible to visualize the gallbladder (dilated or not), gallbladder stones, dilated intrahepatic and extrahepatic bile ducts, stones in the dilated common bile duct, and tumors of the bile duct and porta hepatis. Sonographic investigations were performed in 60 patients with distal biliary obstruction. The cause of the obstruction was recognized in 37 cases (carcinoma of the head of the pancreas was diagnosed in 21 cases, metastases to the porta hepatis in 5, choledocholithiasis in 6, carcinoma of the common bile duct in 3, pancreatitis in 2). The cause of the obstruction was not recognized in 23 cases; it was determined by subsequent investigations to be carcinoma of the head of the pancreas and papilla in 8 cases, metastasis to the porta hepatis in 1, choledocholithiasis in 10, carcinoma of the common bile duct in 1, carcinoma of the gallbladder with metastases in 1, and papillary stenosis in 2. The findings indicate the great value of sonography in the diagnosis of biliary obstruction.

7193 COINCIDENTAL OBSTRUCTIVE AND POST-HEPATITIC CHOLESTATIC JAUNDICE. (Eng.) Welsby, P. D.; Smith, C. C.; Ewen, S. W. B.; Brunt, P. W. (Dept. Medicine, Univ. Aberdeen, Scotland). *Postgrad. Med. J.* 53(626):751-752; 1977.

The case of a patient in whom obstructive jaundice due to carcinoma of the pancreas occurred during the cholestatic phase of viral hepatitis is presented. A previously healthy 37-yr-old man developed jaundice, dark urine, and pale stools. Two weeks after the appearance of jaundice, he developed generalized pruritus. An initial diagnosis of virus A hepatitis proceeding to chronic cholestasis was made on clinical and histological grounds and was corroborated by the development of a similar illness with identical histopathological findings in his brother. However, in spite of corticosteroid and cholestyramine therapy, the pruritus and jaundice persisted. The liver became progressively enlarged and irregular, and at this stage the gallbladder became palpable. The patient then developed liver failure, ascites, and renal failure. Abdominal paracentesis revealed serous fluid containing many adenocarcinoma cells. At autopsy, there was considerable distention of the gallbladder and common bile duct related to an extensive carcinoma of the head of the pancreas, which proved to be a primary ductal adenocarcinoma. The dangers inherent in the use of corticosteroids in jaundiced patients and in the interpretation of a non-response to such therapy in patients with severe cholestatic jaundice are illustrated by this case.

7194 PROLYL HYDROXYLASE IN THE SKIN OF PATIENTS WITH OBSTRUCTIVE JAUNDICE. (Eng.) Than, T.; McGee, J. O.; Blumgart, L. H. (Glasgow Royal Infirmary, Glasgow, Scotland). *J. Clin. Pathol.* 30(11):1044-1047; 1977.

Prolyl hydroxylase activity was estimated in skin specimens from 24 patients with obstructive jaundic and 25 nonjaundiced patients to investigate the suspicion that wound healing is defective in jaundiced patients. Prolyl hydroxylase activity in two of three batches of skin specimens from the jaundiced patients was approximately 50% of that of the controls, and only one-third of that of the controls in the third batch. There was no detectable difference in prolyl hydroxylase activity between patients jaundiced as the result of bile duct obstruction or as a result of liver disease, and there appeared to be no difference between patients with benign or malignant common bile duct obstruction. The results suggest that jaundice is associated with low skin prolyl hydroxylase levels, and in patients submitted to operation for obstructive jaundice this condition might impair healing. Because this enzyme catalyzes hydroxyproline synthesis in collagen, its reduced level could lead to a diminution in the stability of skin collagen, or the low level is simply an indicator of generali depressed collagen synthesis.

7195 COMMON BILE DUCT OBSTRUCTION ASSOCIATED WITH A DACRON H-GRAFT PORTACAVAL SHUNT. (Eng.) Prinz, R. A.; Pickleman, J. (Loyola Univ. Medical Center, 2160 S. First Ave., Maywood, IL 60153). *Arch. Surg.* 113(3):333-335; 1978.

An unusual case is described in which a Dacron pro thesis, used to perform an H-graft portacaval shu

eroded into the common bile duct, served as a nidus
for stone formation and resulted in ascending cholangitis. A 45-yr-old woman had recurrent bleeding
esophageal varices for which she had been treated
successively with a Dacron H-graft portacaval shunt,
subtotal gastrectomy and Billroth II reconstruction,
and balloon tamponade. When the portacaval shunt
failed to function, intra-arterial vasopressin was
followed by splenorenal shunt, splenectomy, and resection of the tail of the pancreas. Fifteen months
later, the patient presented with fever, chills,
upper right quadrant pain with nausea and vomiting,
and jaundice. A diagnosis of ascending cholangitis
was made; cholecystectomy and operative cholangio-
raphy were carried out. The common bile duct was
ilated and obstructed by thick, inspissated bile
nd friable stone formation. Multiple stones and
he full 2-cm Dacron graft were extracted from the
uct. The Dacron graft and bile yielded, upon cul-
ure, *Escherichia coli*, γ-*Streptococcus* group D,
nd *Proteus mirabilis*. Microscopically, the gall-
ladder revealed fibrous thickening with an acute
nd chronic inflammatory cell infiltrate and focal
reas of micro-abscess formation. Prevention of
his potential complication by aseptic technique
nd by isolating the graft from all other intra-
bdominal organs by the interposition of viable
issue is important.

196 DIFFUSE PAPILLOMATOSIS OF THE BILIARY TRACT.

(Eng.) Jakimowicz, J. J.; Stock-
ann, C. H. J. (Dept. Surgery, St. Franciscus Gast-
uis, Rotterdam, Netherlands). *Arch. Chir. Neerl.*
9(4):255-259; 1977.

he case of a 62-yr-old man with diffuse papil-
omatosis of the biliary tract is reported. The
atient presented with vague upper abdominal symp-
oms, dark urine, colorless feces, and icterus. His
evel of total bilirubin was 240 μM, alkaline phos-
hatase 216 mU/ml, thymol 2 U, SGOT 115 mU/ml,
GPT 93 U/ml; his urine contained bilirubin and
robilin. Liver biopsy suggested congestion in
he biliary tract with pericholangitis. The ic-
erus exacerbated after 1 week, and percutaneous
ranshepatic cholangiography showed a few slightly
ilated intrahepatic bile ducts with several small
illing defects and an obstruction near the hepatic
ilus. Laparotomy revealed numerous small polypous
ucosal tumors in the extrahepatic bile ducts with-
ut signs of intraparietal infiltration. The
rowths were removed as far as possible, a T-drain
as left in the choledochus, and cholecystectomy
as performed. Cytological examination of resected
issues revealed no malignancy. Pathological ex-
mination suggested a benign bile duct papilloma-
osis. The patient was discharged with nearly nor-
l liver functions. One year later, the patient
as readmitted comatose with icterus and with fever
to 40 C; his ESR was 130 mm, WBC 14.2, alkaline
osphatase level 220 mU/ml, and total bilirubin
evel 110 μM. The patient died several days later
om septic shock, probably as a consequence of the
currence of cholangitis and possibly with the
rmation of an intrahepatic abscess.

7197 SPONTANEOUS PERFORATION OF BILE DUCTS IN NEONATES.

(Eng.) Fitzgerald, R. J.; Parbhoo, K.; Guiney, E. J. (Royal Children's Hosp., Flemington Rd., Parkville, Victoria 3052, Australia). *Surgery* 83(3):303-305; 1978.

The cases of three neonates with spontaneous perforation of the bile ducts are reviewed, and the mode of presentation, treatment, and relevant literature are discussed. All three patients appeared to be well for the first 1 to 2 weeks after birth. Nonbile-stained vomiting and acholic stools were present in all three on admission. Marked abdominal distention was evident in two and became so in the third. The liver function tests were normal in all three children, excluding the raised bilirubin levels. Bile cultures were negative in the two infants in whom this was done. All patients were treated by laparotomy in the seventh week, with attempted closure of the perforation and a simple biliary diversion by cholecyst-jejunostomy with jejunojejunostomy below it. The patients have done well, and one is now 12 yr of age. Experience with these patients confirms the belief that, where there is doubt about the patency of the distal bile duct, a diversionary procedure should be performed.

7198 TWO INSTANCES OF BILE REFLUX WITHOUT ACUTE PANCREATITIS.

(Eng.) White, T. T.; Allan, B. J. (Univ. Washington Hosp., Seattle, WA). *Surg. Gynecol. Obstet.* 146(6):917-920; 1978.

The cases of two patients in whom most of the bile and the pancreatic juice were mixed but who did not develop acute pancreatitis are presented. Bile and pancreatic juice were mixed within the pancreatic duct and drained through the tail of the pancreas because of a presumed surgical injury to the ampulla of Vater in the first patient. In the other patient, bile and pancreatic juice were mixed within the bile duct secondary to a tumor of the ampulla of Vater. The amount of active trypsin in the bile-pancreatic juice mixtures from these patients more or less paralleled that of bile-staining. The levels of chymotrypsin did not follow the bile-staining as markedly. Three of four specimens from the first patient passed through the pancreas without activation. None of these samples was visibly bile stained. All of the other specimens showed varying amounts of active trypsin and chymotrypsin, and it was not possible to determine whether activation had occurred in the pancreatic ducts or whether it took place sometime later during collection or storage. These observations indicate that, while bile may have a role in the production of pancreatic disease, additional factors are required to produce acute pancreatitis. It is possible that trypsin inhibitors contained in human bile and pancreatic juice may bind trypsin.

7199 REPAIR OF BENIGN STRICTURE OF THE COMMON BILE DUCT BY JEJUNAL INTERPOSITION CHOLE-

DOCHODUODENOSTOMY. (Eng.) Wheeler, E. S.; Longmire, W. P., Jr. (Univ. California at Los Angeles Sch. Medicine, Los Angeles, CA). *Surg. Gynecol. Obstet.* 146(2):260-262; 1978.

Repair of benign common bile duct stricture by jejunal interposition choledochoduodenostomy is described and discussed. The interposition of an isolated segment of isoperistaltic jejunum from the obstructed common duct to the proximal duodenum was previously reported and used to treat both obstruction of the common duct in the region of the papilla and recurrent cholecystopancreatitis. The procedure has now been carried out with good results in a patient with benign stricture. An isolated jejunal segment (at least 15 cm in length) is placed in a retrocolic position. Jejunal continuity is re-established by an end-to-end anastomosis. The proximal end of the jejunal segment is closed in two layers, and an end-to-side choledochojejunal anastomosis is performed, with an inner row of interrupted catgut sutures and an outer row of interrupted silk sutures. The distal end of the jejunal segment is then anastomosed in two layers to the side of the proximal portion of the duodenum. A long-limbed T tube is placed in the duct with one limb passing through the anastomosis into the jejunal segment to decompress the biliary system in the initial postoperative period. This technique has special advantages, including that (1) the obstruction is relieved by reconstruction with a mucosal-lined structure, (2) bile is drained into the proximal duodenum, making peptic ulceration less likely, (3) the biliary-enteric anastomosis can be performed without tension, lessening the chance of anastomotic leak, and (4) the length of the jejunal segment in an isoperistaltic direction reduces the likelihood of reflux of duodenal contents into the bile duct.

7200 AN ADDED DIMENSION TO THE OPERATIVE CHOLANGIOGRAM. (Eng.) Byerly, W. G.; Fahl, J. C. (Medical Arts Clinic, Hickory, NC). *Abdom. Surg.* 19(11/12):237-241; 1977.

The records of 87 patients undergoing 88 cholecystectomies with or without operative cholangiograms and with or without common bile duct exploration (CBDE) are reviewed to assess the need for operative cholangiography. Operative cholangiograms were performed in 71 patients, and 10 were abnormal. Of these 10, 3 indicated the need for CBDE, which would have been done anyway because of clinical and laboratory findings; these 3 cases were positive at exploration. Another three cases of CBDE were indicated solely on the basis of the operative cholangiograms, and these cases were negative at exploration, giving a false-positive rate of 4% for operative cholangiography. Of 30 patients who had one or more commonly accepted classical indications for CBDE, 22 were not explored because of a normal cholangiogram. Operative cholangiography was useful in indicating the need for CBDE in two patients where it was otherwise unexpected; in one of these cases, the surgeon elected not to perform CBDE, while in the other case, cholangiography demonstrated multiple common bile duct stones. Operative cholangiography was also useful in demonstrating abnormal ductal pathology in two cases. A value or help rate can be established by taking the number of cases in which CBDE was avoided when otherwise indicated (22), adding the number of cases in which CBDE was indicated when otherwise unsuspected and subsequently proved to have been needed (1), and adding the CBDE procedures saved because abnormal anatomy was identified (2). Thus, 25 of 71 procedures were helpful, giving a value rate of 35%. Of 17 cholecystectomies that included a pathologic diagnosis of acute cholecystitis, 11 had normal operative cholangiograms, preventing unnecessary CBDE in 64.7% of such cases. Twelve postoperative complications occurred in nine patients. One patient died on the ninth postoperative day of massive hemorrhagic pancreatitis; this death was felt not to be related to the cholangiogram but rather to the underlying pathology and operative procedure. Operative cholangiography is concluded to be a cost-effective method of limiting unnecessary surgery.

GENERAL

20 A CONTROLLED TRIAL OF TAUROLIN IN ESTAB-
LISHED BACTERIAL PERITONITIS. (Eng.)
owne, M. K.; MacKenzie, M.; Doyle, P. J. (Monk-
nds District General Hosp., Airdrie, Scotland).
rg. Gynecol. Obstet.* 146(5):721-724; 1978.

double-blind controlled trial of taurolin was
dertaken to assess its therapeutic usefulness in
ritonitis. For ethical reasons, the trial was
stopped as soon as a statistical difference between the two groups emerged. The trial solutions contained either 2% taurolin in 5% polyvinylpyrrolidone or 5% polyvinylpyrrolidone alone, both in normal saline. Patients entered the trial if, at operation, they had gross peritonitis or frank fecal soiling and were then shown to have positive swab cultures in Stuart's transport medium. Up to 200 ml of the randomly chosen test solution (coded A or B) was

instilled prior to closure of the abdomen or afterward via a tube drain. An additional 200 ml could be instilled daily, if required, for up to 7 days. When only 35 patients had entered the trial, solution B proved statistically superior, so the code was broken, and it was confirmed that solution B contained taurolin. A normal recovery with normal wound healing and no sepsis was taken as a good result, and all other outcomes were classified as bad. By this criterion, solution B was statistically more beneficial than solution A ($p<0.01$). The choice of antibiotics was ruled out as having influenced the outcomes. Of 17 patients in group A, 3 died (one of massive pulmonary embolus, causing his removal from the analysis); there were no deaths among the 18 patients in group B. There was a tendency for older patients and women to respond poorly, but neither difference was significant. The morbidity was 39% in group B and 70% in group A. The treatment of severe peritonitis is briefly reviewed. Taurolin is an intraperitoneal antiseptic at least as effective as noxytiolin and easier to use clinically; even in small doses it has a significant effect on morbidity, if not on mortality, over and above powerful antibiotics. It appears to be nontoxic.

7221 CIMETIDINE IN THE MANAGEMENT OF THE ZOLLINGER-ELLISON SYNDROME. (Eng.) Larkworthy, W.; Davies, H. L. (RAF Hosp., Nocton Hall, Nocton, Lincoln, England). *Postgrad. Med. J.* 53 (1626):749-750; 1977.

The case of a patient with the Zollinger-Ellison syndrome who was treated from the outset and continuously for over a year with cimetidine is reported. The patient, a 70-yr-old man, presented with dyspepsia, vomiting, and diarrhea that had occurred in increasingly severe episodes since he had undergone vagotomy and partial gastrectomy 4 yr earlier; the operation had been carried out because of evidence of pyloro-duodenal ulceration, but a carcinoid tumor was found in the pyloro-duodenal region. Endoscopy revealed severe inflammation and multiple ulcers in the lower esophagus and stomach. A giant ulcer involved much of the anterior wall of the stomach and there was also a deep penetrating ulcer of the posterior wall. The gastrectomy stoma was ulcerated throughout its circumference. Basal gastric secretion studies showed a volume of 320 ml/hr and acid secretion of 28.8 nmol/hr. After the patient developed melena and a partial thickness myocardial infarct, cimetidine therapy (200 mg 3 times/day and 400 mg at night) was started. Within 20 min of taking the first tablet, his symptoms disappeared and have not returned. Marked endoscopic improvement was observed as early as 1 month after therapy was begun, with healing of esophageal, gastric, and stomal ulcers.

GENERAL

Parasitology

39 SEROLOGIC DIAGNOSIS OF EXTRAINTESTINAL AMEBIASIS: A COMPARISON OF STICK-ELISA OTHER IMMUNOLOGICAL TESTS. (Eng.) Felgner, (Bernhard-Nocht-Institut fur Schiffs- und Tropen-nkheiten, Bernard-Nocht-Str. 74, 2000 Hamburg W. Germany). *Tropenmed. Parasitol.* 28(4):491-; 1977.

value of the heterogenous enzyme-linked immuno-bent assay (ELISA) in the diagnosis of amebiasis compared with that of complement fixation, in-ect hemagglutination, counterelectrophoresis, latex agglutination in 37 patients with amebic er abscesses and in 20 healthy controls. The ctivity of all sera from the patients exceeded t of the controls in ELISA. There was a positive relation between the extinction values of ELISA the results of indirect hemagglutination and nterelectrophoresis at the 1% level. These re-ts confirm that extraintestinal amebiasis can diagnosed with ELISA.

0 AMEBIC PERITONITIS FOLLOWING RUPTURE OF AN AMEBIC LIVER ABSCESS: SUCCESSFUL ATMENT OF TWO PATIENTS. (Eng.) Wallace, R. J., ; Greenberg, S. B.; Lau, J. M.; Kalchoff, W. Mangold, D. E.; Martin, R. R. (Baylor Coll. Medicine, Houston, TX 77030). *Arch. Surg.* 113(3): 322-325; 1978.

The cases of two patients who were successfully treated for amebic peritonitis secondary to rupture of an undiagnosed liver abscess are presented together with a clinical discussion of this complication of hepatic amebiasis. A 37-yr-old man with no history of liver disease presented with fever, dark urine, intermittent right-sided abdominal pain, distended abdomen, decreased bowel sounds, and mild scleral icterus. Abdominal roentgenograms revealed scattered loops of small bowel and a ground glass appearance of ascites. When his condition deteriorated (elevated pulse and temperature, increased pain, disorientation), an exploratory laparotomy revealed a ruptured abscess of the inferior portion of the right lobe of the liver. Numerous trophozoites of *Entameba histolytica* were present in biopsy specimens. Treatment consisted of drainage of the abscess and abdomen, emetine (65 mg/day, i.m. for 6 days), clindamycin and gentamicin for 48 hr, and metronidazole (750 mg, p.o., t.i.d. for 6 days after emetine was discontinued). The patient became asymptomatic, although at 6 months his liver scan was still abnormal. A 36-yr-old man presented with fever, malaise, right-shoulder pain, watery diarrhea, severe right lower quadrant abdominal pain, and diminished bowel sounds. A chest roentgenogram revealed a probable pleural effusion with elevation of the right hemidiaphragm. Exploratory laparotomy revealed a ruptured hepatic abscess in the superior portion of the right lobe; the abscess and abdomen were drained. Because insufficient tissue was available for histological evaluation of amebic involvement, a serum sample was assayed by counterimmunoelectrophoresis and was positive for precipitins to *E. histolytica*. Treatment consisted of clindamycin and gentamicin for 48 hr and emetine (65 mg/day, i.m., for 6 days) followed by metronidazole (750 mg, p.o., t.i.d. for 8 days). The patient was asymptomatic at 3 months with a minimally abnormal liver scan. The diagnosis of amebic liver abscess should be considered in anyone with a suspected liver abscess, jaundice, or diarrhea in whom peritonitis develops, especially in a patient who has been to Mexico. The optimal therapy for amebic peritonitis is unproved. Surgical intervention is often necessary. Emetine alone or followed by metronidazole after surgical drainage is presently the treatment of choice.

GENERAL

Regional Enteritis

7261 ABNORMAL GALLIUM SCAN IN REGIONAL ENTERITIS. (Eng.) Joo, K. G.; Landsberg, R.; Parthasarthy, K. L.; Bakshi, S. P. (Buffalo General Hosp., Buffalo, NY). *Clin. Nucl. Med.* 3(4):134-136; 1978.

A report of abnormal gallium scan in a case of regional enteritis is presented. A 41-yr-old woman presented with fever, intractable diarrhea, anorexia, and frequent abdominal cramps of 3 months' duration. She had lost 20 lb., was pale and weak, and had a diffusely tender abdomen. A bone marrow biopsy revealed active hematopoiesis and prominent granulocytic hyperplasia without evidence of tumor and the patient was suspected of having regional enteritis. A gallium scan was performed to rule out lymphoma. Two successive scans showed intense uptake of ^{67}Ga in the pelvis as a large, well-circumscribed area of abnormal accumulation, confirming the presence of an inflammatory and/or neoplastic pelvic disease. Radiologic examination of the small bowel demonstrated multiple dilatations of the ileum with interspersed segmental narrowing, cobblestone mucosal pattern, and some areas of vertical ulceration. These changes were most prominent in the terminal ileum, indicating regional enteritis. The site of the abnormal ^{67}Ga uptake corresponded to the ileal lesions seen on the small bowel x-ray. The patient responded to i.v. ACTH and antibiotics, which were replaced after 10 days by p.o. prednisone. Gallium scanning appears to be a useful procedure in evaluating patients with granulomatous inflammation, especially regional enteritis, and it may prove helpful in identifying actively involved sites of disease.

7262 INHERITED DEFICIENCY OF SECOND COMPONENT OF COMPLEMENT AND HLA HAPLOTYPE A10,B18 ASSOCIATED WITH INFLAMMATORY BOWEL DISEASE. (Eng.) Slade, J. D.; Luskin, A. T.; Gewurz, H.; Kraft, S. C.; Kirsner, J. B.; Zeitz, H. J. (Rush Medical Coll., Chicago, IL). *Ann. Intern. Med.* 88(6):796-798; 1978.

Histocompatibility locus antigen studies and studies of the complement system were carried out in a patient with C2 deficiency, inflammatory bowel disease, sacroiliitis, and haplotypes A10,B18 and Aw32,B18 at the major histocompatibility locus and in a family in which all three members had severe inflammatory bowel disease and two had the A10,B18 haplotype. In the patient, serum total complement and C2 hemolytic complement activities were undetectable; levels of the remaining C1-C9 components were normal. The parents, both siblings, and a child of this patient each had half-normal levels of C2 and either the A10,B18 or the Aw32,B18 HLA haplotype. In a second unrelated family, an only child and both parents developed inflammatory bowel disease. The father and child had HLA haplotype A10,B18, but, along with the mother, each had normal serum levels of hemolytic C and C2. Homozygous C2 deficiency, often in association with the A10,B18 haplotype, has previously been linked with various autoimmune diseases and with propensity to infection. The present findings suggest that C2 deficiency or this haplotype also may predispose to inflammatory bowel diseases.

7263 MALIGNANT LYMPHOMA COMPLICATING REGIONAL ENTERITIS: CASE REPORT AND REVIEW OF THE LITERATURE. (Eng.) Collins, W. J. (St. Joseph Hosp., 1100 W. Stewart Dr., Orange, CA 92668). *Am. J. Gastroenterol.* 68(2):177-181; 1977.

The case of a patient with malignant lymphoma complicating regional enteritis is presented and the relevant literature is reviewed. The patient, a 63-yr-old man, had 9 yr of clinical symptoms and small bowel x-ray changes involving more than 50 cm of ileum and considered diagnostic of regional enteritis. At laparotomy, a segment of ileum was found to be adherent to the sigmoid colon, and fistulous tracts were identified. There was also recent free ileal perforation with peritoneal fecal soiling. The diseased segment and a portion of the cecum were removed surgically, and the histological features of the resected tissue included infiltration of a thickened bowel wall with acute and chronic inflammatory cells including numerous lymphocytes as well as some large histiocytes. The inflammatory changes were interpreted as regional enteritis with an associated peritonitis secondary to fecal spillage. The patient subsequently developed right upper quadrant tenderness and hypotension, a subhepatic abscess, a fistulous tract between the common bile duct and right upper quadrant surgical incision site, pyrexia, and massive gastrointestinal bleeding. A malignant lymphoma of the mixed histiocytic-lymphocytic type was diagnosed after the examination of another segment of ileum and colon. This is the sixth case in which malignant lymphoma developed in small intestine involved with regional enteritis. The duration of illness in this patient is incompatible with a diagnosis of lymphoma, as published series of untreated primary small intestinal lymphomas do not have 5-yr survivals.

PREFACE

GASTROENTEROLOGY ABSTRACTS and CITATIONS is a publication of the National Institute of Arthritis, Metabolism and Digestive Diseases. This specialized information medium has been initiated to fill an existing great need in the field of gastroenterology and to assist the Institute in meeting its obligations to foster and support laboratory and clinical research into the nature, causes, and therapy of diseases of the gastrointestinal tract. Publication GASTROENTEROLOGY ABSTRACTS and CITATIONS makes available citations of all current papers relevant to this field from medical journals published throughout the world. Approximately one-third of the citations dealing with the major aspects of gastroenterology have accompanying abstracts.

The issuing of GASTROENTEROLOGY ABSTRACTS and CITATIONS under the auspices of the National Institute of Arthritis, Metabolism, and Digestive Diseases will provide a much needed current awareness tool to scientists and will facilitate greater integration of research and clinical efforts in this field. The number and great diversity of publications in the area of gastroenterology makes it imperative that an appropriate service be available to investigators and practitioners so that they may be apprised of progress with a minimum of delay. Our aim is to provide the readers with a readily systematized compilation of current published work. The publication will provide the greatest usefulness if these interested investigators will contribute their ideas and comments for consideration whenever possible.

GASTROENTEROLOGY ABSTRACTS and CITATIONS is published monthly and includes citations and abstracts from the biomedical world literature as they are currently received. In addition, yearly cumulated subject and author indexes are published.

This publication is available free to National Institutes of Health grantees and contractors working in the field of gastroenterology and libraries of medical schools. Requests from these qualified individuals to receive free copies of this publication must include their grant or contract number and the title of their project. These requests as well as address changes and other communications should be addressed to:

PRE-CLINICAL SCIENCES

MORPHOLOGY, CELLULAR STRUCTURE AND HISTOCHEMISTRY

71 EVIDENCE FOR ARTERIOVENOUS COMMUNICATIONS IN THE GASTROINTESTINAL TRACT. (Eng.)
eonard, J. J.; Emery, R. W.; Einzig, S.; Nicoloff,
. M.; Fox, I. J. (Univ. Minnesota Medical Sch.,
inneapolis, MN). *Surg. Forum* 28:419-421; 1977.

study was carried out in 17 mongrel dogs to
etermine whether arteriovenous communications
VCs) less than 15 μm in size exist in the
astrointestinal tract and, if so, their ef-
ect on gastrointestinal blood flow measurement
a radionuclide-labeled microsphere technique.
ne anesthetized dogs were placed on positive-
essure ventilation, and 10^6 15-μm ^{85}Sn- and 7
10^6 8-μm ^{46}Sc-labeled microspheres were injected
multaneously into the left atrium via a catheter
ile a reference sample was withdrawn from the
rta at a constant rate. After sacrifice, the
astrointestinal organs were excised at 2 min
roup 1, 6 dogs), 15 min (group 2, 5 dogs), or
min (group 3, 6 dogs) following microsphere
jection, and gastrointestinal blood flow measured
the aortic reference sample technique in 1.0-
15-g organ samples. The mean aortic pressure,
eart rate, pH, PO_2, and PCO_2 were similar in all
ree groups. Flow values for the 8-μm micro-
heres were 25-70% (average 48%) lower than
lues for the 15-μm microspheres for all gastro-
testinal organs except the spleen and pancreas,
dicating the early traversal of the smaller
crospheres across the microcirculation in all
t those two organs, with lodgment of these micro-
heres in the liver. The flow rate of 8-μm micro-
heres was much higher than that of 15-μm micro-
heres in the liver (58 versus 21 ml/min/100 g),
dicating traversal across the mesenteric micro-
rculation by the 8-μm microspheres. The re-
lts indicate the presence of AVCs <15 μm in
ze in gastrointestinal organs other than the
ncreas and spleen, regardless of whether these
e normal capillaries or arteriovenous anasto-
ses.

72 LUMINAL DILATATION AND MORPHOLOGIC CHANGES SECONDARY TO ENTEROTOXINS. (Eng.) Udall,
N.; Alvarez, L. A.; Peterson, D. F.; Nichols, B.
(Dept. Pediatrics, Univ. Arizona, Tucson, AZ
724). *Physiol. Chem. Phys.* 9(2):109-116; 1977.

ne validity of interpreting mucosal changes in
osed intestinal loop models in the presence of
evere distention was tested by studying structural
nanges in ligated rat small intestinal loops ex-
osed to purified cholera enterotoxin. Exposure
ligated loops to 20 μg of cholera enterotoxin
ncreased the fluid content from a control level of
05 ± 0.03 ml to 1.86 ± 0.56 ml ($p<0.001$). These
nterotoxin-exposed loops were microscopically ab-
ormal, many having severe shortening of the villi.
another series of experiments, temporarily li-
ated intestinal loops were exposed to cholera enterotoxin, the ligature was removed after 15 min, and the abdominal wall sutured. The animal was sacrificed after 5-6 hr, and a large-bore needle and syringe were used to aspirate open loop luminal fluid from each animal. The average volume of luminal fluid from the controls in the open loop system was 0.3 ± 0.2 ml, whereas that in the enterotoxin-exposed animals was 1.3 ± 0.3 ml ($p<0.005$). The morphology of enterotoxin-exposed loops and control loops were normal. These studies show that distention secondary to increased luminal fluid causes artifactual histologic damage, which questions the validity of interpreting mucosal changes in closed intestinal loop models in the presence of severe distention. The open loop model described eliminates distention as a cause of histologic changes.

7273 THE ULTRASTRUCTURE OF RAT INTESTINAL EPITHELIUM AS REVEALED BY CRYOULTRAMICROTOMY AND TRANSMISSION ELECTRON MICROSCOPY. (Eng. Johnson, I. T.; Bronk, J. R. (Dept. Biology, Univ. York, Heslington, York YO1 5DD, England). *Micron* 8(3):139-143; 1977.

Rat jejunal mucosa, rapidly frozen without the use of cryoprotectants, was sectioned by cryoultramicrotomy and examined by transmission electron microscopy to determine whether this technique is suitable for the study of intestinal transport. The quality of the sections varied with their morphological origin, but acceptable preservation of ultrastructure was obtained near the extremities of the villi. The "ripple" artifact was visible in some sections, and in other sections, the "knitting" artifact, thought to be due to ice-crystal formation, was seen. The brush borders were not disrupted, but they did not exhibit the very ordered appearance with clearly defined microvilli seen in conventionally prepared material. In many areas, the microvilli appeared to be fused into an amorphous layer, and only where some separation occurred was it possible to distinguish them individually. This appeared to be due to the presence of a substantial mucous coat. It is concluded that this procedure is satisfactory as long as the grids are not exposed to the atmosphere for more than a few minutes, which results in artifacts.

ABSORPTION - EXCRETION - TRANSPORT

7281 ELECTRICAL PACING INCREASES JEJUNAL ABSORPTION OF WATER, GLUCOSE, AND SODIUM. (Eng.) Collin, J.; Kelly, K. A.; Phillips, S. F. (Mayo Foundation, Rochester, MN). *Surg. Forum* 28:428-430; 1977.

To determine whether absorption from a segment of small bowel could be increased by backward electrical pacing, a 75-cm segment of proximal jejunum was isolated in each of three mongrel dogs, and the two ends of the segment were fashioned as separate stomas on the anterior abdominal wall. After recovery, each conscious fasted dog was tested on six separate occasions. The test consisted of a 50-g liver meal to induce a fed pattern of intestinal electrical activity, continuous infusion (2.9 ml/min) into the proximal stoma of a glucose (100 mM) plus NaCl (90 mEq/l) solution, and three 30-min periods of measurement in each of which the transit time of a 1-ml bolus of ^{14}C-polyethylene glycol through the loop was determined and in the second of which the segment was driven backward electrically. The electrical stimuli always produced entrainment and backward propagation of pacesetter potentials at the stimulated frequency (16.2/min). The mean time required for transit of 20% of the bolus was significantly longer ($p<0.05$) during pacing than it was either before or after. In each dog, the output of water and the total amount of glucose and sodium collected from the distal stoma were significantly less during pacing than they were either before or after pacing ($p<0.001$-0.02). Backward electrical pacing slows transit time through and increases absorption of water, glucose, and sodium from the isolated canine jejunal segment. This finding may have therapeutic applications in patients with the short bowel syndrome.

7282 CONTRIBUTION OF DIFFUSIVE PATHWAY IN INTESTINAL ABSORPTION OF GLUCOSE IN RAT UNDER NORMAL FEEDING CONDITION. (Eng.) Murakami, E.; Saito, M.; Suda, M. (Sch. Medicine, Ehime Univ., Shigenobu, Onsen-gun, Ehime 791-02, Japan). *Experientia* 33(11):1469-1470; 1977.

The contribution of passive transport in glucose absorption was studied in male Wistar rats by investigating the relationship between the luminal glucose concentration and the absorption rate of glucose. The small intestinal glucose concentration, determined by a specific enzymatic method, was less than 2 mM before feeding and reached a maximum level of 50 mM after feeding a normal meal (laboratory chow). Glucose absorption was studied *in vivo* by circulating various concentrations of glucose through the lumen of the upper half of the small intestine for 15 min. The contribution of passive absorption was studied by eliminating phlorizin-sensitive active transport by the addition of 0.5 mM phlorizin to the glucose solution. The rate of glucose absorption in the presence of phlorizin increased proportionately with an increase in luminal glucose concentration. The difference between the rates in the absence and pre-

:e of phlorizin was saturable, and the half-
.mal concentration of glucose was about 10 mM.
rate of phlorizin-sensitive absorption was
iter than that of the phlorizin-insensitive
orption up to a glucose concentration of ap-
:imately 35 mM, but above this concentration,
opposite was true. These results suggest that
:ose is absorbed mainly via the active trans-
: system when the luminal concentration is low,
that a larger fraction of glucose is absorbed
ι passive process when the luminal glucose con-
:ration is high.

3 INTESTINAL ABSORPTION OF GLUCOSE FROM ISOLATED MICE JEJUNAL LOOPS IN VIVO: CT OF DIFFERENT DERIVATIVES OF TETRACYCLINES.

.) DuHa, S.; Basu, P. S.; Banerjee, S. (Dey's
cal Stores [Manufacturing] Ltd., Calcutta 700
India). *Indian J. Exp. Biol.* 15(6):452-454;
.

effect of different derivatives of tetracyclines
he intestinal absorption of glucose was studied
g isolated mice jejunal loops *in vivo* and
ted mice jejunal sacs *in vitro*. Absorption of
ose (3 mg) from 1 ml of buffer with or without
different tetracyclines (250 μg) by jejunal
s containing six mesenteric blood vessels was
ured *in vivo* in control mice and in mice treated
iously for 7 days with daily i.v. injections
5 mg/kg of tetracycline hydrochloride (TH),
etracycline hydrochloride (OTH), chlortetra-
ine hydrochloride (CTH), or demethylchlortetra-
ine hydrochloride (DTH); the same drug was used
oth the pretreatment and the test on any one
e. In the control mice, glucose absorption in
absence of any drug was 19 ± 1.7 mg/g dry in-
ine/hr, and this level was reduced to 10 ± 1.5,
1.9, 8 ± 1.6, and 11 ± 2 mg/g dry intestine/hr
he presence of TH, OTH, CTH, and DTH, resp.,
he buffer. In mice pretreated with a drug,
glucose absorption (in mg/g dry intestine/hr)
he presence of the same drug was 12 ± 1.4,
2, 12 ± 1.4, and 13 ± 2.5 for TH, DTH, CTH,
DTH, resp. The Na$^+$K$^+$-ATPase activity of the
stinal mucosa (in μg inorganic phosphate [Pi]
rated/mg protein/15 min) was 13.3 ± 2.0, 3.5
5, 6.1 ± 0.44, 1.7 ± 0.28, and 3.0 ± 0.17
controls and TH, OTH-, CTH-, and DTH-treated
, resp. In everted jejunal sacs *in vitro*
ed with glucose (3 mg) in 0.3 ml buffer, the
transferance of glucose/g dry intestine/hr
the mucosal to the serosal surface was 34
and the Na$^+$K$^+$-ATPase activity (as μg Pi lib-
ed/mg protein/15 min) was 13.3 ± 0.64; when
250 μg/ml) was added to the glucose solution,
nean transferance was reduced to 21 ± 1.5
.005) and the ATPase activity to 6.3 ± 0.82
.005). The diminished transport of glucose
ouse jejunum after treatment with different
acyclines appears to be due to an insufficient
gy supply as a result of diminished ATPase
vity.

EFFECT OF DIETARY CARBOHYDRATES ON INTESTINAL TRANSPORT AND ACCUMULATION OF ^{59}Fe^{++} IN IRON DEFICIENT RATS.

(Eng.) Chang, Y. O.; Varnell, T. R. (Div. Biochemistry, Univ. Wyoming, Laramie, WY 82071). *Int. J. Vitam. Nutr. Res.* 47(3):292-295; 1977.

Because *in vivo* studies have indicated that the type of dietary carbohydrate influences the intestinal absorption of iron, a study was carried out to investigate this influence on the active transport of ^{59}Fe^{2++} across the wall of isolated small intestinal tissue and the ability of the tissue to accumulate ^{59}Fe^{++}. Six groups of six male Sprague-Dawley rats were fed 69% carbohydrate iron-deficient diets for 3 weeks. The carbohydrates were cornstarch, dextrin, glucose, fructose, sucrose, or a sucrose-lactose mixture, and measurements were carried out in everted duodenal sacs from sacrificed animals that had been fasted for 12 hr. Only the dextrin-fed rats maintained normal hematocrit values ($p<0.05$), and they exhibited the lowest transfer rate ($p<0.05$) and accumulation of iron ($p<0.05$) of all groups. The rats fed fructose also had significantly lower ($p<0.05$) transfer rates and accumulation of radioiron than did the remainder of the experimental groups. The fructose-fed rats had markedly thicker intestinal walls than did the other groups, which may explain the low transfer rate and absorption of radioiron by this group. The low transfer rate and absorption of iron by dextrin-fed rats is more likely due to altered osmotic relationships in the intestinal wall, producing a slower depletion of body iron reserves during the experimental period. Dietary carbohydrate appears to exert a definite effect on iron metabolism that needs to be further defined.

7285 MORPHOLOGICAL APPEARANCE OF FAT IN THE EPITHELIAL CELLS OF DIFFERENT PORTIONS OF THE INTESTINES IN MICE.

(Eng.) Snipes, R. L. (Zentrum fur Anatomie und Cytobiologie, Justus-Liebig-Universitat, D-6300 Giessen, W. Germany). *Experientia* 33(10):1335-1336; 1977.

Fat absorption was studied morphologically in different segments of the mouse small and large intestines. Mice fasted for 2-3 days were force-fed massive doses of commercial triglycerides (vegetable oil, 0.10-0.15 ml/g) over 2-3 days by gastric intubation. Morphologically, fat appeared as small droplets concentrated in the supranuclear region, presumably in the Golgi region, in the epithelial cells of the most proximal portion of the small intestine. In addition, scattered, fine droplets occurred in the apical cell area. Distal to the duodenum (4-20 cm from the pyloric-duodenal junction), an abrupt increase in the content and size of fat droplets was noted. Fat distribution demonstrated a proximal to distal gradient, being greatest in the mid-jejunal area, but less in the duodenum and ileum. In the cecum and proximal colon, a limited number of fat droplets was observed. The authors stress that the criterion of the amount and size of fat droplets in intestinal epithelial cells does not necessarily give a reliable indication of the efficiency of fat absorption in the different intestinal segments.

ABSORPTION - EXCRETION - TRANSPORT

7286 EFFECT OF VITAMIN D_3 ON DUODENAL ABSORPTIVE CELL PLASMA MEMBRANES: FREEZE FRACTURE REPLICATION STUDY. (Eng.) Jande, S. S. (Dept. Anatomy, Ottawa Univ., Ottawa, Canada). *Cytobios* 17(67/68):171-176; 1976.

Since previous studies have suggested that vitamin D produces alterations in the permeability of the plasma membrane and/or modifies the juxta-luminal complexes, chick duodenal absorptive cells were studied by a freeze-fracturing technique to investigate whether vitamin D also alters the plasma membrane. Immediately after hatching, the chicks were fed a vitamin D-deficient diet for 4 weeks. Some were given i.m. injections of 500 IU of vitamin D_3 24 hr prior to removal of the duodenum. In rachitic as well as vitamin D-replete chicks, the fracture faces of the microvillar as well as lateral and basal plasma membranes revealed the typical structures of plasma membranes described earlier. The PF (convex) faces had numerous, randomly scattered particles of about 8.5 nm in size, whereas the EF (concave) faces had fewer particles. The microvillar membranes had a higher number of particles than did the lateral and basal membranes. Although the number and distribution of particles on the PF faces in the three locations were similar in the two groups of animals, there was a higher number of particles on the EF faces of the membrane from vitamin D-replete chicks than from rachitic chicks. The number of particles were about 0.92 and 2.73 particles/100 nm^2 area in rachitic and vitamin D-replete chicks, resp. In addition, the zonula occludens in rachitic chicks demonstrated a complex arrangement of ridges and grooves, whereas the ridges were fewer in the vitamin D-replete chicks, and many of the ridges showed discontinuities. These changes appear to be related to increased active absorption and passive diffusion of calcium, resp., under the influence of vitamin D_3.

7287 ENHANCEMENT OF IRON ABSORPTION IN IRON DEPLETED RATS BY INCREASING DIETARY FAT. (Eng.) Bowering, J.; Masch, G. A.; Lewis, A. R. (Div. Nutritional Sciences, Cornell Univ., Ithaca, NY 14853). *J. Nutr.* 107(9):1687-1693; 1977.

7288 TRANSPORT OF SODIUM, WATER, 3-O-METHYLGLUCOSE AND L-PHENYLALANINE IN VITRO IN BIOTIN-DEFICIENT RATS [sic] INTESTINE. (Eng.) Petrelli, F.; Coderoni, S.; Moretti, P.; Paparelli, M. (Inst. General Physiology, Univ. Camerino, Camerino, Italy). *Experientia* 33(9):1189-1190; 1977.

THE EFFECT OF MOTILIN ON THE GASTROINTESTINAL PROPULSION IN RATS.

(Eng.) Naka- , S.; Segawa, K.; Hidano, H.; Tsukamoto, Y.; i, M.; Ichikawa, T. (Nagoya Univ. Sch. Medicine, uma-cho, Showa-ku, Nagoya, 466 Japan). *Gas- nterol. Jpn.* 13(1):50-53; 1978.

ric emptying and intestinal propulsion were rmined simultaneously in unanesthetized rats ^{51}Cr method, and the effect of motilin on rointestinal propulsion was studied. Male ar rats received either physiological saline ml, s.c.) or motilin (10, 100, 400, or 1,000 g, s.c.), followed 15 min later by ^{51}Cr-sodium mate via a stomach catheter. Control rats sacrificed at 15, 30, or 60 min and test rats 0 min after ^{51}Cr-label administration. In the rols, the ^{51}Cr label was shown to move through gastrointestinal tract with time. Intragastric oactivity at 15, 30, and 60 min after dosing 55.2 ± 13.8%, 37.3 ± 4.3%, and 15.0 ± 2.8%, ., which illustrates that gastric emptying is arly dependent upon time (semilogarithmic). Motilin at 10 or 100 ng/kg did not sig- cantly affect gastric emptying, but the intra- ric radioactivity was 24.8 ± 5.1% and 25.5 ± at 400 and 1,000 ng/kg of motilin, resp., n represents a significant ($p<0.02$) accelera- of gastric emptying.

SOME POSSIBILITIES FOR PROSTAGLANDIN MEDIATION IN THE CONTRACTILE RESPONSE TO ATP HE GUINEA-PIG DIGESTIVE TRACT.

(Eng.) Kami- , Y.; Serizawa, K.; Shimo, Y. (Dokkyo Univ. Sch. cine, Mibu-machi, Tochigi 321-02, Japan). *Eur. harmacol.* 45(2):199-203; 1977.

nvestigate the mechanism involved in the con- tile responses of the digestive tract to ATP, influence of the prostaglandin synthesis in- tor, indomethacin, and of the prostaglandin gonist, polyphloretin phosphate (PPP), were ined in various longitudinal muscles of the ea pig digestive tract. ATP (10-300 μM) pro- d contractions in esophageal muscularis mu- e, duodenum, jejunum, and ileum and relaxations he gastric body, tenia cecum, ascending colon, rectum. In addition, "rebound" contractions ared in the gastric body, tenia cecum, as- ing colon, and rectum of all animals immedi- y after ATP had been washed out from the organ . Preincubation with 3-20 μM indomethacin for in significantly inhibited esophageal and small stinal contractions induced by ATP, whereas xation of the stomach, tenia cecum, colon, and um was increased. Rebound contractions of latter preparations were also inhibited. The ctive dose of indomethacin for significant fication differed among preparations (e.g., in esophagus and stomach and 10 or 20 μM in stine). The concentrations of indomethacin in each preparation had no effect on the mus- tone of esophagus and small intestine, but de- sed that of stomach, colon, and rectum by t 15% and that of tenia by about 20% of the mal relaxation caused by an application of roterenol (1 μM). PPP (10-100 μg/ml), preincubated for 15 min, produced similar effects in all preparations. Responses of esophagus and stomach were more effectively modified by PPP than were those of intestine (10 or 30 μg/ml versus 50 or 100 μg/ml, resp.). PPP had no effect on esophageal or small intestinal muscle tone, but in the colon and rectum, the relaxation due to PPP was about 10% and in stomach about 25% of the maximal relaxation caused by an application of isoproterenol. The results suggest that prostaglandin release might contribute to the contractile responses of the guinea pig digestive tract to ATP.

7301 EFFECTS OF SOME DRUGS ON THE CIRCULAR MUSCLE OF THE ISOLATED LOWER OESOPHAGUS.

(Eng.) Takayanagi, I.; Kasuya, Y. (Dept. Chemical Pharmacology, Univ. Tokyo, Tokyo 113, Japan). *J. Pharm. Pharmacol.* 29(9):559-560; 1977.

The effects of various drugs on the circular muscle of the lower esophagus and on the esophageal body isolated from the rat and on the lower esophagus isolated from the guinea pig were investigated. Acetylcholine chloride (Ach), cerulein (CE), tetragastrin (TG), and 5-hydroxytryptamine creatinine sulfate (5-HT) contracted the rat circular muscle of the lower esophagus dose-dependently. The dose response curves for CE, TG, and 5-HT were less steep than that for Ach, and the maximum responses relative to that of Ach were 25 ± 9% for CE, 13 ± 6% for TG, and 38 ± 14% for 5-HT. The response to Ach was abolished by atropine sulfate (10^{-7} g/ml), indicating that the site of action of Ach is a muscarinic receptor. An α-adrenoceptor stimulant, phenylephrine hydrochloride (PE, 10^{-7}-10^{-6} g/ml) relaxed the lower esophageal preparation, and the relaxation by PE was greatly reduced by the α-adrenoceptor blocker, tolazoline hydrochloride (10^{-5} g/ml) or phenoxybenzamine hydrochloride (10^{-7} g/ml) but not by a β-adrenoceptor blocker, propranolol hydrochloride (10^{-7} g/ml). The relaxation by a β-adrenoceptor stimulant, (-)-isoproterenol hydrochloride (3×10^{-8} to 10^{-6} g/ml) was abolished by propranolol (10^{-6} g/ml). PE, however, did contract the lower esophageal preparation, even in the presence of propranolol (10^{-6} g/ml). In the circular muscle of the rat esophageal body, Ach caused a dose-related rise in the basal tension of the preparation. TG and CE had no effect on basal tension. Histamine (HA, 10^{-6}-3×10^{-5} g/ml) and Ach (10^{-6}-3×10^{-4} g/ml) contracted the guinea pig lower esophagus. The response to HA was converted to relaxation in the presence of the HA H_1-receptor antagonist, chlorpheniramine maleate. This relaxation was blocked by cimetidine. The results suggest that the circular and smooth muscle of the lower esophagus has physiological and pharmacological characteristics different from the muscle of the esophageal body, and that there are α- and β-inhibitory adrenoceptors in the circular muscle of the rat lower esophagus as observed in the stomach and intestine.

7302 ANAESTHESIA INDUCTION AND LOWER OESOPHAGEAL SPHINCTER PRESSURE.

(Eng.) Laitinen, S.; Mokka, R. E. M.; Valanne, J. V. I.; Larmi, T. K. I. (Dept. Surgery, Univ. Oulu, Oulu, Finland). *Acta Anaesthesiol. Scand.* 22(1):16-20; 1978.

To investigate the effects of some drugs generally used in premedication for, and induction of, anesthesia on the lower esophageal sphincter (LES) and to investigate the effect of the interaction between atropine (AT) and metoclopramide (MC) on the LES pressure (LESP), a study was carried out in 30 mongrel dogs using the esophageal manometric technique. Three groups of 10 dogs each were treated as follows after thiopental (10 mg/kg, i.v.) anesthesia was induced and basal LESP was measured: group I received AT (0.01 mg/kg) followed 5 min later by MC (0.2 mg/kg), both i.v.; group II received AT and MC in reverse order of group I; and group III received succinylcholine (SC, 0.5 mg/kg, i.v.). In group I, AT reduced LESP from 12.6 ± 3.0 mm Hg to 0.8 ± 0.3 mm Hg ($p<0.01$) with maximum effect by 5 min, and subsequent MC administration did not change the lowered LESP. In group II, MC increased LESP from 11.4 ± 2.7 mm Hg to 24.6 ± 5.4 mm Hg ($p<0.01$), and subsequent AT administration did not change the elevated LESP. In group III, SC had no significant lasting effect on LESP, although a transient rise in LESP and in gastric pressure was noted at the depolarization phase. The results indicate that the routine use of MC in premedication for or induction of anesthesia is indicated to prevent the depressant effect of AT on LESP and the possible consequent gastroesophageal reflux, pulmonary aspiration, and postoperative pulmonary complications.

7303 EFFECT OF HYPOVOLEMIC HYPOTENSION AND HYPOVENTILATION ON LOWER ESOPHAGEAL SPHINCTER PRESSURE (LESP). (Eng.)

LiCalzi, L. K.; Biancani, P.; Behar, J.; Kerstein, M. D. (West Haven Veterans Admin. Hosp., West Haven, CT). *Surg. Forum* 28:344-346; 1977.

The effects of hypoventilation and hypovolemic hypotension of lower esophageal sphincter pressure (LESP) were investigated in a cat shock model. Cats were hypoventilated for 15 min via a tracheostomy by reduction in the respiratory rate and tidal volume to a level determined by a PCO_2 approaching twice the basal level (which had been established within the normal range). After 30 min of return to normoventilation, all animals were bled 30% of estimated blood volume over 1-2 min, and hypotension was maintained for 15 min before reinfusion resuscitation. Bethanecol (20 µg/kg i.v.) was administered basally and 2 min before reversal of hypoventilation or hypovolemia. Hypoventilation produced significant hypercapnia (PCO_2, 59 mm Hg, $p<0.001$), acidosis (pH 7.016, $p<0.001$), hypoxia (PO_2, 57 mm Hg, $p<0.05$), and a 12.9% reduction in LESP ($p<0.05$); return to normoventilation increased LESP by 4.5% (not significant). Hypovolemia produced a significant decrease in LESP (29%, $p<0.05$); resuscitation caused a 43.6% increase in LESP ($p<0.05$) above the basal level. In the basal state, bethanecol produced a prompt 75.6% increase ($p<0.05$) in LESP, which was blocked by hypoventilation and by hypovolemia. Return to normoventilation following bethanecol produced a 97% increase in LES ($p<0.05$), and resuscitation produced a 140% increase in LESP ($p<0.05$). The acute effects of hypoventilation on LESP have direct clinical correlations in the patient with respiratory depression of any cause or with pulmonary insufficiency. The blockade of bethanecol by hypoventilation or shock indicates a disorder at the neuromuscular junction or within the smooth muscle of the lower esophageal sphincter.

7304 BRADYKININ ACTION IN THE RAT DUODENUM THROUGH THE CYCLIC AMP SYSTEM. (Eng.)

Paegelow, I.; Reissmann, S.; Vietinghoff, G.; Ro W.; Arold, H. (Dept. Pharmacology Toxicology, Wil helm-Pieck Univ., Rostock, E. Germany). *Agents Actions* 7(4):447-451; 1977.

The effect of bradykinin (BK) on the rat duodena cyclic AMP (cAMP) system was investigated *in vit* and compared with the effect of BK on the rat ut under the influence of different modulators of B action. Duodena from female rats and uteri from estradiolbencoate (200 µg/kg, 16-20 hr before ex ments)-treated rats were used. BK (6 x 10^{-11}-10 M) induced a dose-dependent relaxation of rat du denum; isoproterenol (3 x 10^{-9}-4 x 10^{-6} M) also produced duodenal relaxation. Propranolol (1.8 3.5 x 10^{-5} M) inhibited only the isoproterenol-induced effect. Pretreatment with ACTH (0.003 i munizing U/ml, 5 min) or NaF (10 mM, 2 min) caused significant ($p<0.01$) increases in BK-indu relaxation; the ACTH potentiation continued for min. Theophylline (5.6 x 10^{-5} M) in the bath al potentiated the BK-induced relaxation. Pretreatment with imidazole (1.5 x 10^{-4} M, 2 min) signif cantly ($p<0.05$) inhibited the effect of BK on th duodenum. BK induced a marked contraction in is lated rat uterus; NaF also produced contraction. This contraction was unaffected by ACTH (dose as above), $NaNO_2$ (10^{-4}-10^{-3} M), theophylline (5.6 x 10^{6} or 5.6 x 10^{-5} M), or imidazole (10^{-3} M). BK did not alter the activity of phosphodiesterase (PDE) from plasma membrane fractio of the rat uterus or rat duodenum or of PDE purified from beef heart. Since activators of adeny ate cyclase activity and inhibitors of cAMP-PDE activity potentiate BK activity whereas a cAMP-P activity stimulator reduces BK activity in the duodenum, BK appears to exert its effect on rat duodenum via the adenylate cyclase system. Such effect is absent in rat uteri.

7305 THE EFFECT OF BRADYKININ ON THE ELECTRICAL ACTIVITY OF RAT JEJUNUM. (Eng.

Hardcastle, J.; Hardcastle, P. T.; Flower, R. J. Sanford, P. A. (Dept. Physiology, Sheffield Univ Sheffield S10 2TN, England). *Experientia* 34(5): 617-618; 1978.

To investigate the possibility that kinins may c tribute to the diarrhea that accompanies certain pathological conditions associated with an elev-

:ed blood kinin level, bradykinin (0.01-6 μg,
.v.) was administered to rats, and the potential
ifference (PD) across the jejunum and colon was
easured. Bradykinin caused a rapid and transient
ncrease in PD across both tissues; the response
as dose-dependent and showed a sigmoid relation-
nip to dose in both tissues. Indomethacin (16
;/kg, s.c.) caused no change in the endogenous PD
the two tissues, but it significantly reduced
ne effect of bradykinin; the maximal jejunal re-
ponse was reduced from 4.1 ± 0.6 to 2.9 ± 0.6
(0.01>p>0.001), and the maximal colonic response
as reduced from 3.9 ± 0.8 to 1.7 ± 0.7 mV (0.05>
>0.01). This reduction suggests that bradykinin
erts its effect by stimulating the production of
ndogenous prostaglandins. The possibility that
radykinin contributes to the diarrhea seen in
arcinoid syndrome by inducing a net secretory
tate in the intestine is discussed.

306 EFFECTS OF HYDROCHLORIDES OF AMINO ACIDS IN TEST MEALS ON GASTRIC EMPTYING. (Eng.)
sher, M.; Hunt, J. N. (Guy's Hosp. Medical Sch.,
ndon, England). *Digestion* 16(1/2):18-22; 1977.

extend knowledge of the action of amino acids
gastric emptying, the effects of hydrochlorides
glycine, alanine, arginine, phenylalanine, and
yptophan were studied in four subjects. The sub-
cts received test solutions containing varying
ounts of the hydrochlorides and phenol red via a
omach tube. The gastric contents were recovered
ter 20 min. The volume of the original meal re-
vered was assessed from the amount of phenol red
pirated. In all subjects, increasing the con-
ntration of amino acid hydrochloride in the given
lution caused an increase in the volume recovered.
yptophan hydrochloride and phenylalanine hydro-
loride were significantly more effective than
re the other three ($p<0.01$ and $p<0.05$, resp.).
e slowing of gastric emptying of amino acid hydro-
lorides is consistent with their action as weak
ids. However, the effect of tryptophan and
enylalanine is slightly greater than is predicted
the basis of their actions as acids.

SECRETION AND METABOLISM

7319 IN VITRO EFFECTS OF ELEDOISIN ON AMYLASE SECRETION AND CYCLIC AMP CONCENTRATION OF RAT'S PAROTIDS. (Eng.) DeCaro, G.; Cantalamessa, F.; Giacinti, N. (Istituto di Farmacologia e Farmacognosia, Universita di Camerino, Italy). *Farmaco [Sci.]* 32(9):686-688; 1977.

Preliminary experiments on the *in vitro* effects of eledoisin on the cyclic AMP (cAMP) concentration in rat parotid glands are reported. Slices of rat parotid glands were incubated in eledoisin (50, 100, or 1,000 ng/ml) or in buffer alone (control) for 45 min, after which amylase activity in the medium and cAMP concentration in the tissue were determined and expressed as percentages in comparison with controls (arbitrarily set equal to 100%). Eledoisin produced a dose-dependent increase in amylase activity (138.3 ± 8.2, 196.6 ± 19.4, and 202.7 ± 14.8%, resp., for the 3 doses), but its effect on cAMP concentration was erratic, with both increases and reductions. The mean values indicate a fall in cAMP level with increasing eledoisin dose (76.5 ± 15.2, 75.9 ± 22.3, and 62.1 ± 28.7%, resp., for the 3 doses). It does not appear that eledoisin's stimulatory effect on parotid gland amylase secretion is mediated by cAMP.

7325 THE CYTOPROTECTIVE EFFECT OF MUCOSAL BLOOD FLOW IN EXPERIMENTAL EROSIVE GASTRITIS. (Eng.) Moody, F. G.; McGreevy, J.; Zalewsky, C.; Cheung, L. Y.; Simons, M. (Univ. Utah Coll. Medicine, Salt Lake City, UT). *Acta Physiol. Scand.* (Suppl.):35-43; 1978.

To elucidate the role of mucosal blood flow in the injury that contributes to or follows the breaking of the cation barrier of the gastric secretory epithelium of most mammals, gastric mucosal blood flow (MBF) was studied in anesthetized dogs by aminopyrine clearance or a radioactive microsphere technique. Substances known to enhance ion exchange that disrupt the cation barrier and produce acute erosive gastritis were used: aspirin (20 mM in 0.14 N HCl), alcohol (25% weight/volume), bile salts (20-40 mM sodium taurocholate in 0.14 N HCl), chloromercuribenzene sulfonate (PCMBS, 10 mM in 0.1 M Tris buffer, pH 7.8), and carbenoxolone (0.25% in 1 N saline, pH 7.5). PCMBS caused minimal mucosal injury. The MBF/H^+ back-diffusion ratio was 0.54 ± 0.13 prior to PCMBS and 0.33 ± 0.11 after PCMBS when H^+ loss increased from 1.78 ± 0.63 to 17.8 ± 2.17 μEq/min. When the MBF/H^+ loss ratio was reduced by blood withdrawal (restriction of mucosal perfusion) to 0.07 ± 0.01, massive disruption of the mucosal surface ensued. Carbenoxolone produced a nearly fourfold increase in H^+ to Na^+ exchange and a comparable large increase in mucosal perfusion. The major histological finding was the *in situ* degeneration of mucus cells accompanied by the intracellular solubilization of mucus. Aspirin induced small, multiple, well-circumscribed lesions, but a fourfold increase in mucosal perfusion provided complete protection against injury accompanied by a lesser rate of H^+ back-diffusion. In severe injury, blood flow and H^+ loss were 8.8 ± 0.8 ml/min and -22.3 ± 1.7 μEq/min, resp., whereas in the absence of mucosal injury, these parameters were 36.3 ± 3.4 ml/min and -17.3 ± 2.2 μEq/min, resp. Alcohol injury was mild, with only minimal disturbance in the appearance of the mucosal surface. Bile salts produced a severe injury, with eschar formation over the rugal crest. The results show that in the presence of a rapid rate of H^+ permeation, a decrease in MBF leads to erosive gastritis while an increase in MBF protects gastric mucosa from chemical injury.

7326 MECHANISM OF STRESS ULCER: INFLUENCE OF α-ADRENERGIC BLOCKADE ON STRESS ULCERATION AND GASTRIC MUCOSAL ENERGY METABOLISM. (Eng.) Menguy, R.; Masters, Y. F. (Genesee Hosp., 224 Alexander St., Rochester, NY 14607). *Am. J. Dig. Dis.* 23(6):493-497; 1978.

Experiments were carried out in which splanchnic vasoconstriction during hypovolemia was prevented by α-adrenergic blockade during the state of shock to test the hypothesis that a rapid and profound decrease in mucosal energy metabolism (energy deficit) is responsible for mucosal necrosis during shock-induced gastric mucosal ischemia. Six male albino rabbits subjected to hemorrhagic hypotension for 58-120 min without α-adrenergic blockade all showed severe stress ulceration 60 min after reinfusion, whereas six rabbits subjected to such shock for 120 min with α-adrenergic blockade (phentolamine mesylate, 0.2 g/kg, i.v., followed by 0.02 mg/kg/min until reinfusion) showed no more than minimal gross lesions of stress ulceration (average severity of microscopic mucosal damage on a scale of 0-5 in the fundus, corpus, and antrum were 4.3, 4.2, and 2.5, resp., in the controls and only 1.8, 1.7, and 0.6, resp., in the treated rabbits). In the animals with α-blockade, the indices of mucosal energy metabolism were markedly different from those in animals without blockade. In the former group, the levels of ATP and of ATP + ADP + AMP and the energy charge of the adenylate pool decreased significantly less in all three regions of the gastric mucosa ($p<0.001$-$p<0.05$), and the expected rise of AMP level in the fundus and corpus did not occur in the treated animals. By comparison with unshocked animals, the levels of free glucose, glucose-6-phosphate, fructose-6-phosphate, fructose-1-6-diphosphate, lactate, and pyruvate increased significantly in the fundic and corpus mucosa of all shocked rabbits ($p<0.001$-$p<0.05$), suggesting an increase in the rate of glycolysis. These results support the conclusion that α-adrenergic blockade prevents stress ulceration due to protracted hypotension. The sparing of the mucosa was associated with a significant reduction in mucosal energy deficit, but the association is not sufficient to prove the hypothesis that stress ulceration results from an energy deficit severe enough to cause cell death.

7327 EFFECTS OF CHRONIC PENTAGASTRIN STIMULATION ON PARIETAL CELL SIZE IN RAT GASTRIC MUCOSA. (Eng.) Helander, H. F. (Dept. Anatomy, Univ. Umea, Umea, Sweden). *Acta. Physiol. Scand.* (Suppl.):19-23; 1978.

The effects of chronic pentagastrin stimulation on rat gastric mucosa were studied with quantitative electron microscopical methods to analyze changes that might occur in the size and number of the parietal cells. Eight male Sprague-Dawley rats received pentagastrin injections (250 μg/kg) every 8 hr for 14 days, and eight control rats received no injections. Animals were fasted for 24 hr, with free access to drinking water, before sacrifice. There were no differences between the two groups with respect to ultrastructure of the gastric mucosa; the shape and subcellular morphology of the parietal cells appeared similar in the two groups; the thickness of the mucosa was the same in both groups. The mean profile area of the parietal cells was significantly greater ($p<0.005$) in the stimulated rats (104 ± 9 μm^2) than in the controls (89 ± 7 μm^2). The calculated (estimated) mean volume of the parietal cells was thus 635 ± 76 μm^3 in the control rats and 797 ± 111 μm^3 in the stimulated rats. The volume density of the epithelial cells and of the parietal cells was significantly greater ($p<0.005$) in the stimulated rats (52 ± 4.9% and 16 ± 2.7%, resp.) than in the control rats (44 ± 4.5% and 12 ± 1.5%, resp.). The number of parietal cells per unit volume of mucosa was calculated by dividing the parietal cell volume densities by the mean parietal cell volumes; it was 194,000 ± 24,000/mm^3 in the controls and 198,000 ± 32,000/mm^3 in the stimulated rats. The data show that the trophic effects of chronic pentagastrin stimulation include hypertrophy of the parietal cells.

7328 DIRECT STIMULATORY ACTION OF PENTAGASTRIN ON THE ADENYLATE CYCLASE OF RAT STOMACH MUCOSA.

(Eng.) Nafrady, J.; Wollemann, M. (Univ. Medical Sch., 6701-Szeged, P.O. Box 469, Hungary). *Biochem. Pharmacol.* 26(21):2083-2085; 1977.

The effect of low doses of pentagastrin on adenylate cyclase activity in rat stomach was examined *in vitro*. The basal adenylate cyclase activity of female Wistar rat gastric mucosa particulate cell fractions was significantly enhanced by the addition of either 10^4 M histamine or 33 nM pentagastrin. Doses of pentagastrin as low as 330 pM also caused stimulation. The simultaneous addition of metiamide (10^{-4} M) with histamine (10^{-4} M) completely inhibited histamine-induced adenylate cyclase stimulation, but the administration of 10^{-4} M metiamide with 33 nM pentagastrin had no effect. Because an H_2 receptor antagonist fails to inhibit pentagastrin-stimulated adenylate cyclase activity, pentagastrin receptors must be directly connected with adenylate cyclase in the rat stomach mucosa.

7329 SYMPATHETIC NEUROENDOCRINE REGULATION OF GASTRIC INHIBITORY POLYPEPTIDE RESPONSE TO GLUCOSE.

(Eng.) Sirinek, K. R.; Cataland, S.; O'Dorisio, T.; Mazzaferri, E. L.; Crockett, S.; Pace, W. G. (Ohio State Univ. Coll. Medicine, Columbus, OH). *Surg. Forum* 28:377-379; 1977.

The effect of exogenous sympathomimetic and sympatholytic drugs on both basal and glucose-stimulated gastric inhibitory polypeptide (GIP) release was studied in dogs. The i.v. infusion of isoproterenol (5 μg/kg/hr), propranolol (5 μg/kg/hr), epinephrine (5 μg/kg/hr), norepinephrine (0.5 μg/kg/hr), or dibenzylene (0.5 mg/kg/hr) had no effect on fasting GIP concentrations. Compared with fasting concentrations, incremental GIP was significantly ($p<0.05$) increased at 15, 30, and 45 min for all treatment groups. Compared with intraduodenal glucose alone, the GIP response following intraduodenal glucose (50 ml, 20% glucose) plus i.v. dibenzylene was significantly ($p<0.05$) greater at 15 and 30 min. Compared with glucose alone, the GIP response following glucose and propranolol was significantly ($p<0.05$) less at 15 and 30 min. This study demonstrates both augmentation and blunting of glucose-stimulated GIP release by sympatholytic drugs, suggesting a physiologic role for the sympathetic neuroendocrine system in modulating the GIP response to glucose.

7330 A FAT-ENRICHED MEAL AUGMENTS GASTRIC INHIBITORY POLYPEPTIDE AND SUPPRESSES GASTRIN CONCENTRATIONS.

(Eng.) Tetirick, C. E., Jr.; O'Dorisio, T.; Sirinek, K. R.; Cataland, S.; Pace, W. G. (Ohio State Univ. Coll. Medicine, Columbus, OH). *Surg. Forum* 28:379-380; 1977.

Because it has been previously shown that exogenou gastric inhibitory polypeptide (GIP) suppresses the serum gastrin response to a meal, studies wer carried out to determine whether GIP may physiologically modify gastrin release. GIP release wa stimulated in experimental dogs by feeding a meal containing 67 g of fat (fat-enriched meal). Cont received a meal containing 20 g of fat. The mean change in serum GIP concentration at 75, 90, 105, and 120 min was significantly greater ($p<0.05$) wi the fat-enriched meal than with the control meal. Conversely, the mean serum change in gastrin response was markedly reduced at 75, 90, 105, and 120 min in the fat-enriched meal as compared with the control meal. These results demonstrate that the enrichment of a meal with fat enhances GIP re lease, and that this release is temporally associated with a diminution in serum gastrin respons during the second postcibal hour. This response suggests that endogenous GIP release may physiologically modify meal-stimulated gastrin respons

7331 INTRAVENOUS INFUSION OF AMINO ACIDS STI ULATES GASTRIC ACID SECRETION IN MAN.

(Eng.) Isenberg, J. I.; Maxwell, V. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *N. Engl. J. Med.* 298(1):27-29; 1978.

To determine whether the acid secretory effect of intestinal protein perfusion is in part due to the absorption of amino acids and small peptides from the gut, the effect of i.v. amino acid infusion on gastric acid secretion was studied in six men. The i.v. infusion of 10.6, 21.2, or 42. g of a mixture of L-amino acids significantly ($p<0.05$) stimulated gastric acid secretion. The response to 21.2 and 42.5 g of i.v. amino acids (29.8 ± 7.6 mEq/4 hr at 42.5 g) was similar to th of 42.5 g of intraduodenal amino acids (36.3 ± 6. mEq/4 hr), and was significantly greater ($p<0.05$) than the response to a control i.v. infusion of sodium chloride alone (7.1 ± 3.3 mEq/4 hr). The addition of 250 g of glucose to the i.v. infusio did not significantly alter secretory responses. The serum gastrin level did not significantly change during the i.v. amino acid infusions. The maximal acid secretory response to 21.2 and 42.5 g of i.v. amino acids was approximately one-thir of the response to either intragastric amino aci or the maximal response to pentagastrin. The observation that the secretory response to i.v. amino acids is similar to that produced by small intestinal amino acids suggests that the intestinal phase of gastric acid secretion in man may be mediated totally or in part by the absorption of amino acids from the gut.

7332 STUDIES ON THE ROLE OF SEROTONIN IN GASTRIC PEPSIN SECRETION.

(Eng.) Wanza, M. F.; Stein, T.; Wise, L. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY). *Surg. Gynecol. Obstet.* 146(6):929-932; 1978.

To evaluate further the role of serotonin in pepsin secretion, studies were carried out in eight female mongrel dogs each provided with a Heidenhain pouch and with a gastric cannula to divert the acid secreted by the remaining stomach away from the duodenum. Histamine was infused (0.04 mg/kg/hr) for the entire 4-hr study period; when given alone it constituted the control. When reserpine (0.1 mg/kg, i.m.) was given 24 hr before histamine infusion to deplete the serotonin level, the initial histamine-induced peaks in pepsin concentration (47 ± 20 x 10^3 PU$^{\mathrm{Hb}}$ [hemoglobin substrate]/ml) and output (169 ± 41 x 10^3 PU$^{\mathrm{Hb}}$/ml) were abolished ($p<0.05$). Serotonin replacement by 5-hydroxytryptophan significantly increased ($p<0.05$) both the pepsin concentration (38 ± 12 x 10^3 PU$^{\mathrm{Hb}}$/ml) and output (318 ± 117 x 10^3 PU$^{\mathrm{Hb}}$/ml). The administration of the serotonin antagonist 1-methyl-d-lysergic acid butanol-amide significantly reduced the histamine-induced peaks of pepsin concentration (from 42 ± 7 x 10^3 to 5 ± 3 x 10^3 PU$^{\mathrm{Hb}}$/ml, $p<0.05$) and output (from 213 ± 47 x 10^3 to 20 ± 8 x 10^3 PU$^{\mathrm{Hb}}$/ml, $p<0.01$). These data suggest that serotonin is a stimulator of histamine-stimulated pepsin secretion in denervated gastric pouches in dogs.

7333 UNCOVERING RHYTHMS IN SERUM GASTRIN.

(Eng.) Saik, R. P.; Weisenfeld, N.; Greenburg, A. G.; Kripke, D.; Peskin, G. (Veterans Admin. Hosp., 112E, 3350 La Jolla Village Drive, San Diego, CA 92161). *J. Surg. Res.* 24(5):380-383; 1978.

Because rhythms in acid output have been documented in man without corresponding rhythms in serum gastrin, a study was undertaken in dogs to uncover such rhythms, unencumbered by the influence of feeding, and to assess the importance of diverting acid from the antrum. Peripheral serum gastrin levels were sampled basally and every 2 hr for 24-hr periods in three groups of mongrel dogs fasted with access to water on the day prior to each study (2 studies/dog). In group I (4 normal dogs), a consistent circadian rhythm was evidenced by the nonrandom ($p<0.05$) phase angle distribution of the occurrence of peak gastrins, the circadian amplitude being 100%. In group II (3 dogs in which an innervated antral pouch was exteriorized to eliminate the effects of acidity), the phase angle distribution was random. In group III (5 dogs with innervated antral pouches explanted onto the transverse colon to achieve a hypergastrinemic state), serum gastrin levels were consistently more than double the preoperative levels, but the phase angle distribution was again random. It is concluded that a circadian rhythm of gastrin exists in the dog and is abolished by removing acid or by continuous maximal stimulation, suggesting that the rhythm is dependent on intraluminal pH and independent of vagal activity per se except as this activity may affect acid output. Physiological distention may also play a role in the circadian release of gastrin.

7334 THE ACTION OF INTRAVENOUS ETHANOL ON GASTRIC SECRETION.

(Eng.) Kondo, T.; Magee, D. F. (Nagoya Univ., Nagoya, Japan). *Proc. Soc. Exp. Biol. Med.* 156(2):299-302; 1977.

Experiments were carried out in dogs to test the hypothesis that gastrin is the mediator through which ethanol stimulates gastric secretion. Four dogs with Heidenhain pouches and five with gastric fistulae and innervated antral pouches were used after 18-hr fasts in experiments involving ganglionic and cervical vagal blocks and in experiments with antral pouch acidification, resp. Ganglionic block was induced with pertolinium tartrate (usually 1 mg/kg, s.c.) at the start of ethanol infusion (4 ml/min, i.v. of 10% ethanol) with atropine (1 mg, i.m.) superimposed after 60 min. Cervical vagi were blocked by infiltration anesthesia using 2% Xylocaine to both nerves 30 min after beginning the ethanol infusion. Antral acidification was accomplished by intubation with 0.1 N HCl (10 ml/min), and ethanol infusion was begun when the resting secretion from the stomach was nearly zero. The i.v. infusion of ethanol (control) stimulated fistula acid and pepsin secretion and Heidenhain pouch acid but not pepsin secretion. Ganglionic blockade eliminated ethanol-stimulated fistula acid and pepsin secretion and diminished the pouch acid and pepsin secretion; the addition of atropine reduced pouch and fistula acid secretion to basal levels ($p<0.05$). Cervical vagal block did not suppress either fistula or pouch acid or pepsin secretion. After antral acidification to pH 1, ethanol no longer stimulated fistula acid or pepsin secretion, but a return to pH 7 caused steep increases in both secretions. It is concluded that i.v. ethanol administration stimulates gastric secretion mainly by liberating antral gastrin.

7335 EFFECTS OF ORAL CALCIUM AND MAGNESIUM ADMINISTRATION ON GASTRIC ACID SECRETION AND SERUM GASTRIN CONCENTRATION IN MAN.

(Eng.) Mazzacca, G.; Budillon, G.; D'Agostino, L.; D'Agostino, E.; Buonocore, S. (II Clinica Medica dell'Universita di Napoli, Napoli, Italy). *Rend. Gastroenterol.* 9(2):105-108; 1977.

To examine whether the simultaneous ingestion of calcium and magnesium compounds can abolish the gastric stimulation observed after p.o. calcium ingestion alone, studies were carried out in seven healthy volunteers that had fasted overnight. Test solutions were given by intubation, and gastric secretion and blood were sampled for 2 hr. After 2 g calcium carbonate, gastric acid output increased during the 1st hr in all subjects; after magnesium hydroxide (8.0 ml milk of magnesia), gastric acid output was unchanged in five and decreased slightly in two; and after a combination of the two antacids, gastric acid output was unchanged in four and slightly increased in three. The mean acid secretory response to calcium carbonate was significantly increased above the basal level in both the 1st ($p<0.001$) and 2nd ($p<0.01$) hr, but it was unchanged by magnesium hydroxide or by both antacids together. Ingestion of calcium carbonate alone or calcium carbonate plus magnesium hydroxide produced a significant rise ($p<0.01$) in serum gastrin concentration above the basal level at both 30 and 60 min, but there was no change after magnesium hydroxide ingestion. Because magnesium ingestion antagonizes the effect of p.o. calcium on gastric acid secretion, the use of antacid preparations containing both magnesium and calcium appears warranted in short-term therapy.

7336 SOMATOSTATIN INHIBITS AND REVERSES HYPERGASTRINEMIA INDUCED BY PARATHYROID HORMONE, CALCIUM, AND ACETYLCHOLINE. (Eng.) Bolman, R. M., III; Cooper, C. W.; Garner, S. C.; Wells, S. A., Jr. (Duke Univ. Medical Center, Durham, NC). *Surg. Forum* 28:373-374; 1977.

The effects of somatostatin (somatotropin release-inhibiting factor, SRIF) on gastrin release induced by parathyroid hormone (PTH), calcium, or acetylcholine (ACH) were studied in anesthetized pigs. Test substances were infused directly into the antral circulation via a catheter in the right gastroepiploic artery. Synthetic SRIF (1.67-16.7 µg/min), infused together with PTH (bovine 1-84 or synthetic human 1-34, 0.04-0.4 U/min), prevented the 20- to 30-fold rise in gastrin observed following the infusion of equal doses of PTH alone ($p<0.001$). Infusion of SRIF (1.67 µg/min) together with 0.05 M $CaCl_2$ in five pigs markedly inhibited the large increase in gastrin release produced by $CaCl_2$ alone ($p<0.05$ to $p<0.001$). Infusion of SRIF (3.34-16.7 µg/min) together with 0.1 M ACH largely inhibited the 10- to 20-fold rise in gastrin observed following infusion of ACH alone in four of six pigs ($p<0.05$ to $p<0.005$ in 3 of 4 pigs). Infusion of SRIF (1.67-16.7 µg/min) after stimulation of gastrin secretion by PTH, $CaCl_2$, or ACH produced a rapid and pronounced decrease in gastrin secretion (after PTH, -75%, $p<0.005$ in 3 pigs; after Ca, -79%, $p<0.025$ in 3 of 4 pigs; after ACH, -86%, $p<0.05$ to $p<0.001$ in 5 pigs). It is concluded that SRIF inhibits gastrin release induced by PTH, Ca, or ACH and also reverses a hypergastrinemia evoked by any of these secretagogues. SRIF is thus a useful tool for studying mechanisms involved in gastrin release.

7337 GASTRIN STIMULATED H^+ SECRETION IN AMPHIBIAN GASTRIC MUCOSA: EFFECT OF TETRODOTOXIN. (Eng.) Spenney, J. G. (Veterans Admin. Hosp., Birmingham, AL 35294). *Experientia* 34(5): 625-626; 1978.

The role of neural mechanisms in gastrin-stimulated H^+ secretion was studied in amphibian gastric fundic mucosa using tetrodotoxin, a compound that blocks neural Na^+ channels. Adult bullfrog mucosa was mounted in an *in vitro* preparation. The initial H^+ secretion rate was measured, and then burimamide (10^{-4}-10^{-3} M) was added to the serosal solution; H^+ secretion was totally inhibited. Tetrodotoxin (3.0×10^{-6} M) and then pentagastrin (3.3×10^{-6} M) were added to the serosal solution. Burimamide produced a rise in transmucosal potential difference (PD) and resistance (R) coincident with H^+ secretion inhibition. Tetrodotoxin added to either the spontaneously-secreting or resting mucosa had no effect on H^+ secretion and no consistent or significant effect on PD or R. Pentagastrin added in the presence of tetrodotoxin was an effective stimulant of gastric H^+ secretion (the average rise was to 5.22 µmol/cm^2/hr from 0); the PD and R decreased. The failure of tetrodotoxin to block gastrin stimulation of H^+ secretion indicates that neural mechanisms are not required.

7338 EFFECT OF VAGAL STIMULATION ON THE CONCENTRATION OF GASTRIN IN SERUM AND ANTRAL MUCOSA IN DOGS. (Eng.) Watayou, T.; Ramus, I.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX 77550). *Arch. Surg.* 113(1):87-89; 1978.

The rapidity and duration of gastrin release at the antrum after electrical stimulation of the vagus nerve were assessed in dogs, and the changes in gastrin concentration in antral mucosa that result from this vagal stimulation were measured. Electrical vagal stimulation produced a significant increase in the circulating serum gastrin concentration at 1 min to 1 hr after the initiation of the stimulus ($p<0.05$). After 1 hr of continued stimulation, the antral gastrin concentration also increased significantly ($p<0.02$). The results suggest that vagal release of gastrin triggers its rapid synthesis.

7339 GASTRIN: OBLIGATORY INTERMEDIATE IN THE POSTPRANDIAL MOBILIZATION OF GASTRIC HISTAMINE IN THE RAT. (Eng.) Hakanson, R.; Hedenbro, J.; Liedberg, G.; El Munshid, H. A.; Rehfeld, J. F. (Dept. Pharmacology, Univ. Lund, Lund, Sweden). *Experientia* 33(11):1541-1543; 1977.

The effects of antral gastrin and of vagal excitation on postprandial histamine release in the rat were investigated. Adult male Sprague-Dawley or Wistar rats underwent radical antrectomy (pyloric gland area, the adjacent portion of the oxyntic gland area, and the duodenal bulb) with great care to eliminate the entire lesser curvature. The nervous and vascular supply to the remainder of the stomach was spared. After recovery, all rats were fasted 48 hr; group 1 remained fasted (control), group 2 received food for 1 hr, and group 3 received pentagastrin s.c. After sacrifice at dif-

ent times over a 5-hr period, serum gastrin was
ermined radioimmunochemically, the oxyntic mu-
al histamine level was determined fluorometri-
ly, and oxyntic histidine decarboxylase activity
determined radiometrically. In unoperated
ted rats, feeding raised the serum gastrin con-
tration ($p<0.001$), reduced the mucosal histamine
centration ($p<0.001-0.01$), and activated histi-
e decarboxylase activity ($p<0.001$) to signifi-
t degrees; feeding failed to elicit any of these
ects in antrectomized rats. In unoperated fasted
s, pentagastrin reduced the histamine concentra-
n over the first 2 hr ($p<0.001-0.01$) and acti-
ed the histidine decarboxylase activity ($p<0.001$).
operated, fasted rats, the basal histamine level
lower than in control rats, but they still re-
nded to pentagastrin administration with re-
tion of the histamine level (significant at 1
$p<0.001$) and activation of histidine decarboxy-
e activity ($p<0.001-0.01$). It is concluded that
ral gastrin is an obligatory mediator of the
tprandial activation of histidine decarboxylase
mobilization of histamine.

n-METHYL, 5-METHYL HISTAMINE EVOKES A
HIGHER MAXIMAL RATE OF GASTRIC ACID SE-
TION THAN HISTAMINE. (Eng.) Impicciatore, M.;
taccini, G.; Mossini, F.; Hansen, D.; Grossman,
I. (Veterans Admin. Wadsworth Hosp. Center, Los
eles, CA 90073). *Proc. Soc. Exp. Biol. Med.*
(2):296-298; 1977.

effects of the histamine H2 receptor antagonist
ethyl, 5-methyl histamine (dimethylhistamine,
on acid secretion in gastric fistula cats
investigated. When graded doses of DMH (10-
20 µg/kg/hr) or histamine (10-640 µg/kg/hr) were
en i.v. at 30-min intervals, the maximal re-
nse to DMH was significantly greater than that
histamine ($p<0.02$). When graded doses of hista-
e (80-2,560 µg/kg/hr) were given i.v. at 30-min
ervals with and without a constant background
the histamine H1 receptor antagonist pyrilamine
mg/kg loading dose plus 2 mg/kg/hr), the max-
l response to histamine plus pyrilamine was
nificantly greater than that to histamine alone
.02). When graded doses of DMH (320-5,120 µg/
hr) were given i.v. at 30-min intervals with
without a constant background of histamine
uble the dose needed for maximal response), the
imal response to DMH was significantly lower
the presence of histamine ($p<0.02$) than in its
ence. The maximal response to the combined
gs was similar to the maximal response to his-
ine alone. These findings are compatible with
hypothesis that, in addition to the well known
ion of histamine on H2 receptors, it also acts
H1 receptors to inhibit gastric acid secretion.

EFFECT OF CIMETIDINE ON ION FLUXES AND
POTENTIAL DIFFERENCE ACROSS THE HUMAN
MACH. (Eng.) Ivey, K. J.; Mackercher, P. A.
t. Medicine, Univ. Missouri, Columbia, MO 65201).
19(5):414-418; 1978.

letermine whether the reduction of acid output by cimetidine in man is due entirely to a reduction in acid secretion or whether increased back diffusion of hydrogen ions is also occurring, fluxes of H^+, Na^+, K^+, and Cl^- ions after acid instillation into the stomach were studied in six healthy subjects with and without prior p.o. administration of 300 mg cimetidine. Potential difference across gastric mucosa was measured continuously throughout each study. Cimetidine caused a significant reduction in hydrogen ion secretion (5.05 mEq/15 min in controls versus 2.70 mEq/15 min with cimetidine, $p<0.05$), and consequently a significant reduction in net hydrogen flux into the gastric lumen (2.01 mEq/15 min versus 0.02 mEq/15 min, resp., $p<0.05$). There were no significant differences between sodium ion fluxes in control and cimetidine studies, suggesting that the gastric mucosal barrier remained intact. Cimetidine alone caused a highly significant rise in intragastric pH (to 7) and of potential difference ($p<0.001$). Addition of intragastric acid (pH <1.0) did not reverse the rise in potential difference caused by cimetidine, suggesting that factors other than change in intragastric pH were involved. These studies support the concept that reduction in acid output by cimetidine is due to inhibition of acid secretion, and not to increased permeability to hydrogen ion.

7342 CIMETIDINE AND PROSTAGLANDIN: EVIDENCE FOR DIFFERENT MODES OF ACTION ON THE RAT GASTRIC MUCOSA. (Eng.) Carmichael, H. A.; Nelson, L. M.; Russell, R. I. (Royal Infirmary, Glasgow G4 OSF, Scotland). *Gastroenterology* 74(6):1229-1232; 1978.

Studies were carried out in rats to determine whether cimetidine, like prostaglandin E_2 methyl ester ($Me\text{-}PGE_2$), inhibits aspirin-induced gastric mucosal erosions. The effects of cimetidine and $MePGE_2$ on aspirin-induced gastric mucosal erosions in the continual presence of HCl were also measured. Cimetidine (50 mg/kg) significantly inhibited ($p<0.01$) gastric mucosal erosions induced by aspirin (192 mg/kg), reducing the incidence from 70% of 20 rats to 9.5% of 21 rats; the mean lesion score was reduced from 9.3 ± 2.1 to 0.4 ± 0.3. The effect of the above doses of $Me\text{-}PGE_2$ and cimetidine on gastric erosions induced by aspirin (192 mg/kg) were compared with the hourly addition of 160 mM HCl. The incidence of erosions in the aspirin plus HCl group was 100% of 20 rats (mean lesion score 27.4 ± 2.4). This incidence was not significantly reduced by cimetidine, the incidence being 90% of 20 rats (mean lesion score 19.7 ± 3.4). The incidence of erosions in the presence of $Me\text{-}PGE_2$ was significantly less than that in both the other groups (13% of 23 rats; mean lesion score 3.1 ± 0.8, $p<0.01$ in both instances). These results suggest that, whereas cimetidine protects the gastric mucosa through acid inhibition, $Me\text{-}PGE_2$ appears to have a protective effect independent of acid inhibition.

7343 EFFECTS OF BLOOD GLUCOSE LEVELS ON ASPIRIN-INDUCED GASTRIC MUCOSAL DAMAGE. (Eng.) MacDonald, A.; Dekanski, J. B.; Gottfried, S.; Parke, D. V.; Sacra, P. (Biorex Lab. Ltd., Canonbury Villas, London N1 2HB, England). *Am. J. Dig. Dis.* 22(10):909-914; 1977.

To investigate the effects of fasting and other procedures that affect blood glucose levels on the susceptibility of rats to aspirin-induced (200 mg/kg, p.o.) gastric mucosal damage, female Biorex Wistar rats were studied under various conditions. In rats fasted for 18 hr, blood glucose levels decreased ($p<0.001$), the incidence (100% versus 45% in controls) and severity ($p<0.002$) of mucosal damage increased, and gastric glycoprotein synthesis decreased by 50% ($p<0.05$) compared with controls; glucose (50 mg/ml) in the drinking water prevented these changes. Fed rats with alloxan-induced (100 mg/kg, s.c., for 5 days) diabetes were similar to controls in terms of aspirin-induced mucosal damage and glycoprotein synthesis, but 18-hr fasted diabetic rats had greater incidence (100% versus 50% in controls) and severity ($p<0.05$) of aspirin-induced mucosal damage and greatly decreased glycoprotein synthesis (to 33% of control value, $p<0.01$). In nondiabetic rats, insulin (10 U/kg, s.c.) followed by the removal of food caused a significant fall in blood glucose level ($p<0.001$), an increase in the incidence (100% versus 50% in controls) and severity ($p<0.02$) of aspirin-induced mucosal lesions, and a significant decrease in glycoprotein synthesis (to 19% of control, $p<0.05$) Insulin treatment of alloxan-induced diabetic rats did not change their susceptibility to aspirin-induced mucosal damage (60%) or its severity or the extent of glycoprotein synthesis when compared with untreated diabetic rats. *In vitro* incubation of mucosal homogenates with 10^{-4} M dibutyryl cyclic AMP or 10^{-4} M theophylline decreased glycoprotein synthesis significantly ($p<0.05$) to 60% and 62%, resp., of control, but incubation with dibutyryl cyclic GMP (10^{-4} M) had no significant effect. The results indicate that hypoglycemia may be a factor in the susceptibility of rats to aspirin-induced gastric mucosal damage and that cyclic AMP may be involved in the synthesis and secretion of mucus from gastric mucosal cells.

7344 EFFECTS OF HISTAMINE, PENTAGASTRIN AND ACETYLCHOLINE ON CANINE GASTRIC SECRETION IN VITRO [Abstract]. (Eng.) Kuo, Y. J.; Shanbour, L. L. (Univ. Texas Medical Sch., Houston, TX 77030). *Fed. Proc.* 37(3):697; 1978.

7345 H^+ TRANSPORT: REGULATION AND MECHANISM IN GASTRIC MUCOSA AND MEMBRANE VESICLES. (Eng.) Sachs, G.; Spenney, J. G.; Lewin, M. (Lab. Membrane Biology, Univ. Alabama, Birmingham, AL). *Physiol. Rev.* 58(1):106-173; 1978.

7346 MUCOSAL LESIONS DUE TO GASTRIC DISTENSION IN THE RAT. (Eng.) Gati, T.; Guth, P. H. (Semmelweis Medical Sch., Budapest, Hungary). *Am. J. Dig. Dis.* 22(12):1083-1090; 1977.

SECRETION AND METABOLISM

Pancreas

7371 BIOCHEMICAL STUDIES OF PANCREATIC JUICE COLLECTED BY DUODENAL ASPIRATION AND ENDOSCOPIC CANNULATION OF THE MAIN PANCREATIC DUCT.

(Eng.) Escourrou, J.; Frexinos, J.; Ribet, A. (Clinique des Maladies de l'Appareil Digestif, C.H.U. de Rangueil, 31054 Toulouse Cedex, France). *Am. J. Dig. Dis.* 23(2):173-177; 1978.

The collection of pancreatic secretion by a classical duodenal aspiration technique was compared with collection by cannulation of Wirsung's duct under duodenoscopic control in the same seven fasted, healthy subjects. In both cases, the same stimulants were used: 0.5 clinical U/kg/hr of GIH secretin and 75 ng/kg/hr of cerulein, given in a saline chloride infusion over 1 hr. The pH determined to the nearest 1/100 unit was found to be significantly higher ($p<0.05$) in samples collected by cannulation than in samples collected by aspiration. The mean of volumes for every subject showed no significant difference between pure pancreatic juice (PPJ, 104 ± 20.07 ml/30 min) and duodenal aspirate (DA, 103.8 ± 37.53 ml/30 min). However, the variance was greater in the DA ($S2=1,645.5$) than in the PPJ ($S2=441.8$). The bicarbonate concentration in the PPJ (124.51 ± 11.32 mEq/l) was significantly greater than that in the DA (76.14 ± 9.30 mEq/l, $p<0.001$), as was the bicarbonate output (429.4 ± 80.37 versus 260 ± 94.5 μEq/min). There was a linear relation between the weight of the subject and the bicarbonate output measured in the PPJ ($r=0.81$). There was no statistical separation between the mean concentrations and outputs of protein, lipase, chymotrypsin, and amylase determined in the DA and in the PPJ. The results show that, in the normal subject, the collection of pancreatic juice obtained by endoscopic cannulation of the main pancreatic duct is necessary to explore the maximal secretory capacity of water and electrolytes. However, this technique is no better than the present method of duodenal aspiration with stimulation by secretin or cerulein for the exploration of the enzyme secretion.

7372 THE POLAR INTERACTIONS BETWEEN PANCREATIC LIPASE, COLIPASE AND THE TRIGLYCERIDE SUBSTRATE.

(Eng.) Borgstrom, B.; Donner, J. (Dept. Physiological Chemistry, Univ. Lund, POB 750, S-220 07 Lund, Sweden). *FEBS Lett.* 83(1): 23-26; 1977.

The type of bonding interaction that occurs between pancreatic lipase and colipase on one hand and the bile salt-laden substrate interface on the other was investigated using porcine and rat pancreatic juice, various triglyceride substrates, and a 2-mM Tris-maleate buffer (pH=7.0) in 1 mM $CaCl_2$ with varying concentrations of NaCl and bile salt. In some cases, the pH of the buffer was varied. In the absence of bile salts, lipase adsorbed completely to the tributyrin (substrate) interface and NaCl (up to 1 M) did not affect the binding. In the presence of bile salt above the critical micellar concentration (4 mM taurocholate), the binding of lipase to tributyrin depended on the salt concentration, the pH of the solution, and the pI of the enzyme. At low salt concentration, rat lipase bound substrate up to pH 7.5 and above M NaCl, no binding occurred at any pH. The bindin curve over pH shifts to the left as the salt concentration rises, as does the pH optimum for the enzyme. In the absence of NaCl, both lipases bound to three different oil/water interfaces (tributyrin, trioctyl glyceryl ether, hexadecane) to the same extent. Addition of NaCl drove the lipase into the aqueous phase; the NaCl concentration required to accomplish this shift depended on the interface structure, being lowest for hexadecane, higher for the ether, and highest (>0.1 M) for the ester. The adsorption of colipase to tributyrin was unaffected by NaCl (0-1 M) in the absence of bile salt; above 4 mM taurocholate, increasing the NaCl concentration decreased the adsorption with no adsorption occurring at 1 M. When trioctyl glyceryl ether was used in the presence of >4 mM taurocholate at pH 7.0 and 150 mM NaCl, no colipase adsorption occurred. The results demonstrate that polar rather than hydrophobic bonding is important for the attachment of lipase and colipase to their bile salt-laden substrates at the substrate oil/water interface. It is suggested that the specific bonding of these two proteins to their substrates occurs via hydrogen bonds to substrate carbonyl groups.

7373 A STUDY OF THE SYNTHESIS OF DNA, RNA, PROTEIN, AND OXYGEN UPTAKE IN SEGMENTS OF THE RAT PANCREAS.

(Eng.) Adams, H. W.; Webste P. D., III (Medical Coll. Georgia, Augusta, GA). *Am. J. Dig. Dis.* 22(10):898-901; 1977.

To determine whether there is metabolic uniformity among segments of the pancreas, the synthesis of DNA, RNA, and protein and oxygen uptake were studied *in vitro* in the head (parabiliary and duodenal segments), body (gastric segment) and tail (splenic segment) of the pancreas of male Sprague-Dawley rats. There was no significant difference in the DNA content (except that the tail segment averaged 10% less DNA/mg wet tissue than did the body or head, $p<0.05$), RNA content expressed in terms of DNA, or protein content expressed in terms of DNA among the three segments. The rates of DNA synthesis (incorporation of ^3H-thymidine), RNA synthesis (incorporation of ^3H-uridine), and protein synthesis (incorporation of ^{14}C-phenylalanine) were not significantly different among the three segments, nor was the oxygen

ptake (consumption) in the three segments sig-
ificantly different. The lower DNA content in
he tail of the pancreas suggests that, on a per
eight basis, there are fewer cells and more con-
ective tissue or other structural elements in
his segment. It is concluded that there is meta-
olic uniformity in the rat pancreas and that one
egment of the pancreas may be considered to be
epresentative of the entire pancreas metabolically.

374 EFFECT OF PANCREATIC POLYPEPTIDE ON DNA-SYNTHESIS IN THE PANCREAS. (Eng.) Green-
erg, G. R.; Mitznegg, P.; Bloom, S. R. (Royal
ostgraduate Medical Sch., London W12, England).
xperientia 33(10):1332-1333; 1977.

 study was carried out in 48 male Sprague-Dawley
ats that had been fasted for 24 hr to determine
hether pancreatic polypeptide (PP) has any trophic
ffect in the gastrointestinal tract and to estab-
ish whether PP can influence the trophic action
f cholecystokinin (CCK). Four groups of 12 rats
ach received single i.p. injections of NaCl
group I, control), CCK-octapeptide (CCK-OP, 18
mol/kg, group II), bovine PP (BPP, 12 nmol/kg,
roup III), or both CCK-OP and BPP (same doses,
roup IV). After 15 hr, each animal received an
njection of 0.5 mCi/kg ^{3}H-thymidine, and all ani-
als were sacrificed at 16 hr and the liver, pan-
reas, duodenum, and oxyntic area of the stomach
xamined for incorporation of label. The drugs
ad no significant effect on DNA synthesis in
ither the liver or duodenum. In the pancreas,
he extent of DNA synthesis was significantly in-
reased by both CCK-OP ($p<0.05$) and BPP ($p<0.01$)
ompared with the control; BPP did not affect the
nhancement elicited by CCK-OP. The extent of DNA
ynthesis was increased twofold by all three treat-
ents; the level following CCK-OP plus BPP treatment
as significantly greater than the control value
$p<0.005$). Although in the duodenum, both CCK-OP,
P, and the combined drugs enhanced the ex-
ent of DNA synthesis 50% compared with controls,
he differences did not reach statistical signif-
cance. BPP has a trophic effect on the pancreas
d duodenum, but it neither augments nor inhibits
he trophic action of CCK-OP.

75 EFFECT OF EXPERIMENTAL HEMORRHAGIC PANCREATITIS ON RESPIRATORY FUNCTION AND
LMONARY PHOSPHOLIPIDS. (Eng.) Dougall, A.
; Brennan, M. M.; Wong, C. Y.; Harding, P. G.
; Possmayer, F.; Ahmad, D.; *et al.* (Univ. Hosp.,
iv. Western Ontario, London, Ontario, Canada).
rg. Forum 28:189-191; 1977.

 study was undertaken to correlate the degrada-
on of pulmonary phospholipids with the deter-
oration of pulmonary function during acute pan-
reatitis in dogs. Acute pancreatitis was in-
ced in five dogs by the transduodenal injection
 0.5 ml/kg of autologous bile; controls were
am operated. Normal saline (10 ml/kg/hr, i.v.)
s given during the whole 12-hr experiment, during
ich respiratory function was measured and after
which the animals were sacrificed and phospholipids recovered from lung lavages and sera for analysis by two-dimensional thin-layer chromatography. Phospholipase A activity was also determined. Controls demonstrated an improvement in respiratory function over 12 hr, but dogs with pancreatitis suffered a deterioration in function after an initial improvement during the first 8 hr. Lung wash from control dogs contained a greater amount of phospholipid (3.32 ± 0.487 mg/kg body weight) than did lung wash from dogs with pancreatitis (2.11 ± 0.225 mg/kg). The phospholipid composition was similar in both groups (phosphatidyl choline and lysolecithin were 75% and 1.09%, resp., in the control group and 70% and 1.52%, resp., in the experimental group of the total phospholipid) and both components lowered surface tension (in an artificial alveolus machine) to the same degree. Phospholipase A activity was markedly increased in the serum and lung wash of dogs with pancreatitis compared with control dogs. Despite the deterioration of pulmonary function in acute pancreatitis, degradation of pulmonary phospholipids is not detected. Elevated phospholipase A activity in acute pancreatitis does not alter pulmonary surfactant within the first 12 hr of pancreatitis.

7376 TIME COURSE OF PANCREATIC PROTEIN SYNTHESIS FOLLOWING FEEDING. (Eng.) Malo, C.; Morisset, J. (Dept. Biology, Sherbrooke Univ., Sherbrooke, Quebec J1K 2R1, Canada). *Am. J. Dig. Dis.* 23(1):6-8; 1978.

To establish whether the effects of pancreozymin (PZ) and secretin (SE) on the exocrine pancreas are physiological, the effects of feeding on pancreatic protein synthesis were investigated in male albino Sprague-Dawley rats fasted for 24 hr and then fed five consecutive 1-hr meals of ground rat chow (morning and evening for 2 days plus the 3rd morning). After another 24-hr fast, control rats went unfed but experimental animals were fed for 15 min; rats were sacrificed at 15-min intervals between 15 and 120 min after the last meal. ^{3}H-L-phenylalanine (^{3}H-L-phe, 10 Ci/mmol, 10 μCi) was injected 10 min before sacrifice, and then the pancreas was homogenized for study. The free intrapancreatic ^{3}H-L-phe pool did not change significantly over time. But the incorporation of the radiolabel into protein was significantly reduced ($p<0.001$) 45 min after the end of the meal and significantly increased by 90 min ($p<0.05$) and 105 min ($p<0.02$) after the meal compared with controls. The rate of incorporation returned to the control level by 120 min. The results show that feeding induces variations in total pancreatic protein biosynthesis *in vivo*; these variations are similar to those previously observed with PZ and SE, indicating that the changes observed following hormonal stimulation are physiological.

7377 SOMATOSTATIN THERAPY OF ACUTE EXPERIMENTAL PANCREATITIS. (Eng.) Lankisch, P. G.; Koop, H.; Winckler, K.; Folsch, U. R.; Creutzfeldt,

W. (Dept. Medicine, Univ. Gottingen, Gottingen, W. Germany). *Gut* 18(9):713-716; 1977.

Because somatostatin (SRIF) reduces exocrine pancreatic secretion, its effect on acute experimental pancreatitis was investigated in the rat. Acute pancreatitis was induced in 45 male Wistar rats by the retrograde injection of 0.6 ml of 0.8, 2.0, or 3.0% Na-taurocholate into the pancreatic ducts; linear SRIF was given s.c. during the operation as a 200-μg bolus and by infusion (100 μg/100 g body weight) for 3 hr after, while controls received saline infusions. Rats were sacrificed 1 hr after treatment was stopped. SRIF therapy significantly lowered the serum lipase levels in all three groups ($p<0.05$ for 0.8 and 3%, $p<0.001$ for 2%) and the serum amylase level in the 0.8% group ($p<0.02$). Ascites amylase and lipase and pancreatic amylase and trypsin levels as well as the degree of pancreatic necrosis, edema, and WBC count were not affected by SRIF. When the same protocol was used to induce 2%, 2.5%, or 3% Na-taurocholate pancreatitis in 56 rats, all rats (SRIF-treated and control) in the 3% group died within 20 hr, 50% of the treated and 50% of the control rats survived in the 2.5% group, and 73% of the treated and 75% of the control rats survived in the 2% group. SRIF does not appear to be effective in the treatment of acute pancreatitis.

7378 INHIBITORY EFFECT OF SOMATOSTATIN ON HUMAN PANCREATIC POLYPEPTIDE SECRETION. (Eng.) Marco, J.; Hedo, J. A.; Villanueva, M. L. (Clinica Puerta de Hierro, Universidad Autonoma, Madrid, Spain). *Life Sci.* 21(6):789-791; 1977.

The effect of somatostatin on the secretion of human pancreatic polypeptide (HPP) was investigated in five patients who had undergone subtotal gastric resection with Billroth I or Billroth II reconstruction due to benign ulcer disease. Overnight fasted patients underwent an oral glucose tolerance test (OGTT) during which plasma HPP levels were determined. Glucose (1.75 g/kg) was taken 60 min after starting a somatostatin (9 μg/min after an initial 250 μg bolus) or saline infusion; the entire test lasted 3 hr. The mean fasting plasma HPP level was 65 ± 10 pg/ml. Glucose ingestion during saline infusion caused a prompt elevation of the plasma HPP level ($p=0.02$, $p=0.01$, $p=0.006$, and $p=0.01$ at 10, 15, 20, and 30 min, resp.). When somatostatin was infused, the plasma HPP level was depressed compared with the basal level ($p=0.0007$-0.005), and the HPP response to p.o. glucose was completely abolished. These results demonstrate that somatostatin is a potent inhibitor of pancreatic polypeptide secretion in man.

7379 EXOCRINE PANCREATIC RESPONSE TO THE VENOM OF THE SCORPION, Tityus trinitatis. (Eng.) Bartholomew, C.; Murphy, J. J.; McGeeney, K. F.; Fitzgerald, O. (General Hosp., Port-of-Spain, Tri dad, West Indies). *Gut* 18(8):623-625; 1977.

Because acute pancreatitis has been reported afte the sting of the scorpion, *Tityus trinitatis*, the effect of its venom on exocrine pancreatic secret was investigated in dogs. A dose of 1 mg/kg veno usually stimulated pancreatic volume, amylase, lipase, and trypsin output. In one dog receiving this dose, pancreatic output was increased from a basal level of 0.42 ml to 0.92 ml, and the amylas lipase, and trypsin levels increased from 0.6 Kal likrein Units (KU) to 10.7 KU, from 47.7 KU to 19 KU, and from 4.1 mg to 16.7 mg, resp. The pancreatic response of one dog to serial injections of venom (1.0 mg/kg) produced an increasing rate of enzyme secretion with repetition of the stimulus. In another dog, venom was administered during a continuous secretin infusion (16 U/hr, i.v.). A very slight increase in volume resulted, but the enzyme output increased from 0.3 KU to 2.8 KU amylase. The concentration of the secreted enzym increased from 0.15 KU to 1.1 KU/ml. The results indicate that venom from *T. trinitatis* evokes enzyme-rich pancreatic secretion.

SECRETION AND METABOLISM

Hepatobiliary Tract

386 HEPATIC VENOGRAPHY OF NORMAL AND REGENERATING DOG LIVER. (Eng.) Enge, I.;
latmark, A.; Bergan, A. (Rikshospitalet, Oslo 1,
rway). *Scand. J. Gastroenterol.* 13(1):27-32;
978.

otal and selective hepatic vein angiographies
ere performed preoperatively and 6 weeks after
% liver resection in six mongrel dogs to study
e hepatic vein system in the normal and regen-
rating liver. After 6 weeks, the dogs were sac-
ficed for postmortem studies. At 6 weeks post-
eratively, total hepatic venography revealed
5 remaining visible lobar veins, the inferior
na cava, 1 or 2 phrenic veins, and the renal
ins. The inferior vena cava was sometimes slight-
displaced to the left. In one dog, a moderate
t constant narrowing of the inferior vena cava
the level of the diaphragm was seen. The di-
eter of the lobar veins and their major tribu-
ries were increased compared with preoperative
udies, and the lobar veins were elongated and
stributed to a larger mass of hepatic tissue.
e larger subdivisions of the lobar veins were
ven off at strikingly larger angles. Selective
bar vein angiography more distinctly visualized
e smaller peripheral tributaries in the lobes and
owed them to be similar to the preoperative state.
autopsy, the residual livers were all of the
me shape, with the right lateral and caudate
bes obviously increased in size and with thick-
ed, rounded margins, and the regenerated liver
ight was 100-108% of the calculated preoperative
ight. Except for a few small veins emptying
rectly into the inferior vena cava, the hepatic
in anatomy may be evaluated by these angiographic
thods. The results are consistent with previous
dings. The increased diameter of the lobar
ns is probably due to increased blood flow, the
ngation of the vessels and increased angle be-
en the vein radicles to the diffuse growth of
liver remnants, and the narrowing of the in-
ior vena cava in one dog to the surgical pro-
ure.

7387 STUDIES ON SYMPATHETIC INNERVATION OF THE HEPATIC VASCULATURE. (Jpn.) Yamamoto, K. (Kumamoto Univ. Medical Sch., Kumamoto, Japan). *J. Kumamoto Med. Soc.* 51(2):73-89; 1977.

To study sympathetic innervation of the hepatic vasculature, the distribution of norepinephrine fluorescence (NAF) was studied in hepatic arteries and veins of the dog, rabbit, guinea pig, rat, and mouse. Adrenergic receptors were studied in perfused livers by adding sympathetic amines and their blockers to the perfusate. NAF distribution was similar in all species examined. NAF was present in the layer between the adventitia and the media of the intrahepatic artery and the portal vein. NAF was not detected in the hepatic lobuli, including the area adjacent to the central vein. Most of the NAF in the hepatic vein was located in the media, with a small amount in the adventitia. NAF content of the hepatic vasculature was markedly increased after norepinephrine treatment. NAF was markedly decreased after the administration of reserpine. NAF decreased in the hepatic artery and portal vein following periarterial neurectomy in the hepatic hilus or celiac ganglionectomy in rats and dogs, whereas hepatic vein NAF remained unchanged. In perfused canine livers, there was a significant change in flow rate in both the hepatic artery and the portal vein within 30 min of the addition of phenylephrine or isoproterenol to the perfusate. The effects of these drugs were suppressed by phenoxybenzamine or propranolol pretreatment. In the hepatic artery, the flow rate decreased within 30 min of the addition of norepinephrine; this was followed by an increase in the next 30 min of perfusion. Phenoxybenzamine treatment prior to norepinephrine treatment increased the flow rate, whereas propranolol pretreatment decreased the flow rate in the hepatic artery. The flow rate remained unchanged in the portal vein. The results indicate that adrenergic nerve terminals are located between the adventitia and the media of the hepatic artery and portal vein and in the media of the hepatic vein. Alpha- and beta-adrenergic receptors are present in the hepatic artery and the portal vein.

7388 SULFOBROMOPHTHALEIN AND INDOCYANINE GREEN BINDING BY THE HEPATIC CYTOPLASMIC PROTEINS. (Eng.) Namihisa, T.; Nambu, M.; Yamashiro, Y. (Juntendo Univ., Sch. Medicine, 1-1 Hongo 2-chome, Bunkyo-ku, Tokyo, 113 Japan). *Gastroenterol. Jpn.* 12(6):466-468; 1977.

BSP and indocyanine green binding by hepatic cytoplasmic proteins was examined by G-100 Sephadex gel filtration in liver specimens from normal humans, from patients with Rotor's hyperbilirubinemia or the Crigler-Najjar syndrome, and from Wistar rats. In the rat, three peaks, designated X, Y, and Z proteins, were prominent, and preferential localizations of BSP and ICG binding to these proteins were demonstrated. In the human liver, BSP localized to Y protein could hardly be demonstrated, whereas ICG binding was detected. The pattern in the tissues from patients with hyperbilirubinemia or the Crigler-Najjar syndrome was similar to that in the normal subjects. These results suggest that the impaired hepatic organic anion transport in congenital hyperbilirubinemia is probably not related to cytoplasmic organic anion binding proteins.

7389 THE METABOLIC INTEGRITY OF HEPATOCYTES IN SUSTAINED INCUBATIONS. (Eng.) Dickson, A. J.; Pogson, C. I (Biological Lab., Univ. Kent, Canterbury, Kent CT2 7NJ, England). *FEBS Lett.* 83(1):27-31; 1977.

To produce a biochemically verified viable preparation of nondividing parenchymal cells that can be maintained in incubation for 8-12 hr to study hepatic anabolism, the biochemical stability of isolated rat parenchymal hepatocytes incubated in Eagle's minimum essential medium with fetal calf serum (medium B) was studied. The results were compared to those obtained from the same cells incubated with Krebs-Henseleit bicarbonate with bovine serum albumin (medium A). Gluconeogenesis from lactate and ATP content were used as measures of metabolic integrity. Gluconeogenic capacity in hepatocytes from 48-hr starved rats decreased rapidly during a 4-hr incubation in medium A, and this decrease correlated with a decreased hepatocyte ATP content; the decreased ATP content was also found using fed-rat hepatocytes and had a half-life of 2-5 hr. Storage of the cell preparations on ice slowed the metabolic deterioration by 300%. Addition of various substrates, hormones, soybean trypsin inhibitor, and collaginase antibody to medium A did not retard the observed hepatocyte deterioration. However, when hepatocytes were incubated in medium B, the ATP content was maintained for 8 hr of incubation and even at 16 hr was 2.5 times greater than in cells incubated in medium A. The initial cellular activities of lactate dehydrogenase and the ratio of lactate to glutamate dehydrogenases were similar in cells incubated in both media, but the subsequent leakage of lactate dehydrogenase into the medium was greatly retarded in medium B. Although cellular K^+ content was maintained in both media A and B, that of cells in medium B was higher throughout. The results indicate that isolated hepatocytes can be maintained in physiological states for up to 8 hr with little alteration in viability and that medium B appears to be the medium of choice.

7390 BIOCHEMICAL AND ULTRASTRUCTURAL EVALUATION OF ISOLATED RAT LIVER SYSTEMS PERFUSED WITH A HEMOGLOBIN-FREE MEDIUM. (Eng.) Sugano, T.; Suda, K.; Shimada, M.; Oshino, N. (Dept. Veterinary Physiology, Coll. Agriculture, Univ. Osaka Prefecture, Sakai, Osaka 591, Japan). *J. Biochem.* 83(4):995-1007; 1978.

To determine the viability of isolated rat livers perfused with a hemoglobin-free medium devoid of albumin, ultrastructural evaluation and quantitative measurement of several hepatic functions were made in anesthetized male Sprague-Dawley rats perfused in a flow-through mode. The perfusion medium was a mixture of 115 mM NaCl, 5.9 mM KCl, 1.2 mM $MgCl_2$, 1.2 mM NaH_2PO_4, 1.2 mM Na_2SO_4, 2.5 mM $CaCl_2$, and 25 mM $NaHCO_3$. The effect of flow rate on oxygen consumption and changes in the respiratory rate were studied. Ultrastructural changes indicative of liver injury were sought along with changes in metabolism or hormonal response. When the perfusion flow rate was maintained between 3 and 3.5 ml/min/g of liver, all the biochemical parameters measured in the perfused liver system (the rates of glucose, pyruvate, and lactate production, the rate of oxygen consumption, and the tissue contents of adeni nucleotides) were similar to those observed in perfusion systems containing erythrocytes or albumin. Electron microscopy confirmed adeuate preservation of fine structure in all parts of the liver for at least 70 min of perfusion at the flow rate of 3-3.5 ml/min. Hormonal responses demonstrated the operation of integral liver functions in the perfused liver under the experimental conditions. The viability of liver perfused in the hemoglobin- and albumin-free system was confirmed, and this system was found to be equivalent to macromolecule-containing and complex perfusion systems provided an adequate flow rate was employed. The hemoglobin-free system allows analysis by various physicochemical techniques and allows continuous measurement of various parameters. The use of the flow-through mode of perfusion will open a variety of biochemical approaches to the study of hepatic metabolism.

7391 EFFECTS OF PORTACAVAL END-TO-SIDE ANASTOMOSIS ON THE LIVER OF RATS. (Ger.) Rasenack, U.; Grun, M.; Liehr, H. (Medizinische Univ.-Klinik Wurzburg, Josef-Schneider-Str. 2, D-8700 Wurzburg, W. Germany). *Z. Gastroenterol.* 15(11): 680-690; 1977.

The effect of portacaval end-to-side anastomosis on the liver was studied in 117 young rats (liver weight 9.9 ± 1.6 g) and in 33 old rats (liver weight 19.5 ± 1.9 g) and compared with the condition of the liver in 48 sham-operated male Chbb rats. The weight of the liver of the young rats decreased to 7.5 ± 1.7 g 3 days after the operation; the hepatic atrophy was also accompanied by a reduction of the body weight. The cell necrosis of the hepatic parenchyma was most intense during the first 2 weeks, especially during the 2nd and 3rd days after operation. Complete necrosis of the hepatic epithelium and of the reticuloendothelial system was seen in the old rats 48 hr after operation. No particular changes were seen in the livers of the sham-operated rats. Less marked necrosis of individual cells or cell clusters was seen in both groups even after 5-8 months, at a time when endotoxinemia was detected in 85% of the animals by the Limulus test. Loss of glycogen on the peripheries of the lobules and varying degrees of hemosiderosis were seen several months after operation. The atrophic and necrotic alterations seen immediately after operation were due to hemodynamic disorders, because the hepatic artery, although dilated to the maximum, was unable to compensate for the decrease in the portal blood flow. The late necrotic changes were, however, due to endotoxinemia rather than to persisting hemodynamic disorders.

7392 EXPERIMENTAL STUDIES ON HEPATIC HEMODYNAMICS AND FUNCTION IN POSTSINUSOIDAL BLOCK.

(Eng.) Kawabe, K.; Yokota, T.; Mizumoto, R.; Honjo, I. (Faculty Medicine, Kyoto Univ., Sakyo-ku, Kyoto, 606, Japan). *Arch. Jpn. Chir.* 46(5):551-562; 1977.

Hemodynamic changes and liver function were investigated in post- and presinusoidal block in 47 adult mongrel dogs. There were two treatment groups; in group 1, the right branches of the portal vein and the left hepatic vein were ligated to produce presinusoidal block in the right half and postsinusoidal block in the left half of the liver and in group 2, the left hepatic vein was constricted with tape before construction of the portacaval anastomosis. In both acute and chronic (8 weeks after operation) experiments, there was reversed flow from the left half of the liver into the portal vein in group 1. The ratio of blood flow per gram of liver in the right to that in the left half was 1:0.602 in the acute experimental group and 1:0.984 in normal dogs ($p<0.05$). In the chronic group, the hepatic artery flow was the same in the left and right halves, indicating a return to normal flow after the initial acute block. In group 1, the ratio of bile flow from the right to that from the left half of the liver in both acute and chronic conditions showed no significant difference. In the acute tests, there was no difference in BSP excretion between the two liver sections; in the chronic group, however, BSP excretion from the liver lobes with postsinusoidal block was significantly reduced ($p<0.05$). There was severe damage (necrosis and vacuolar degeneration) to the left half of the liver but few changes in the right half in group 1 after 8 weeks. There was little damage to liver cells and no fibrosis in group 2 dogs. In dogs from group 2, the arterial blood entering the left half of the liver flowed out partly via the constricted hepatic vein and partly via the portal vein in a reversed flow. These results indicate that liver function may decrease due to the ineffectiveness of the hepatic artery reversed flow even when the liver cells show only mild changes.

7393 THE DEMONSTRATION OF PHARMACOLOGICALLY ACTIVE SUBSTANCES IN THE PORTAL VEIN BLOOD OF DOGS AFTER THE LIGATION OF THE SUPERIOR MESENTERIC ARTERY.

(Ger.) Wedell, J.; Schmutzler, W.; Kayser, D. (Chirurgische Klinik, Kreiskrankenhaus, D-4900 Herford, W. Germany). *Langenbecks Arch. Chir.* 344(2):131-140; 1977.

The effect of ligation of the superior mesenteric artery on the concentrations of pharmacologically active substances (serotonin, kinins, catecholamines, histamine, and prostaglandin-$F_{2\alpha}$) in the portal vein blood was studied in male and female dogs. The serotonin concentration increased from 0.932 ng/ml in the controls to 0.94 ng/ml during the ligation, and from 0.72 to 5.12 ng/ml during the reopening of the occluded artery. During occlusion, the catecholamine concentration was 0.83 ng/ml versus 0.41 ng/ml in the controls; during reopening, the concentrations were 0.33 ng/ml in the controls, and 0.37 ng/ml in the experimental animals. The kinin concentrations were 0.02 and 0.01 ng/ml in the controls during occlusion and reopening, resp.; the corresponding levels in the experimental animals were 0.064 and 0.04 ng/ml. The histamine levels were 11.5-16.5 ng/ml during occlusion and 11.8-14.3 ng/ml during reopening in the control animals versus 14.5-14.7 ng/ml and 14.8-15.5 ng/ml, resp., in the experimental group. The prostaglandin level was increased only immediately after the occlusion and the reopening of the superior mesenteric artery. While the additive effect of the subthreshold concentrations of these substances cannot be excluded, the measured concentrations in the portal vein blood were too low to be responsible for the development of peptic erosions of the stomach as observed after occlusion of the superior mesenteric artery.

7394 THE EFFECT OF ACUTE ETHANOL ADMINISTRATION ON PHOSPHORYLETHANOLAMINE UPTAKE AND METABOLISM IN RAT LIVER SLICES.

(Eng.) Corazzi, L.; Arienti, G.; Tirillini, B.; Arienti, U. G.; Porcellati, G.; Orlando, P. (Medical Sch., 06100 Perugia, Italy). *Farmaco (Sci.)* 32(8):614-621; 1977.

The possibility that phosphorylethanolamine (PE) is incorporated into liver phospholipids in both normal and acutely ethanol-intoxicated female Wistar rats was investigated using an *in vitro* assay employing liver slices and both ^{14}C-PE and ^{32}P-PE. Experimental and control rats were fasted for 12 hr, then received either 50% ethanol (6 g/kg, single p.o. dose) or 0.9% saline (7.5 mg NaCl/100 g, single p.o. dose), and were sacrificed 8 hr later. Triacylglycerols accumulated in the livers of ethanol-treated rats (8.19 ± 0.90 μmol/g tissue) compared with controls (3.85 ± 0.56 μmol/g). The ratio of $^{32}P:^{14}C$ in PE in the liver was very close to 1 (the theoretical value) after 10-15 min of labeling (and was no less than 0.66 after 60 min), indicating that PE was not hydrolyzed before uptake by liver cells; the ratio was similar at each time point in treated and control animals, indicating no significant differences in uptake between the two groups. Some of the PE was hydrolyzed to free ethanolamine (EA) and orthophosphate, the hydrolysis being less pronounced in the treated rats (77.89 ± 17.35 and 117.57 ± 26.69 nCi labeled EA/g tissue in treated and control rats, resp.). Ethanolamine glycerophospholipids (EPG) were strongly double-labeled to similar extents in both treated and control rats; the labeling ratio was very high initially (0.83 in both groups after 10 min of labeling) and fell to 0.47 and 0.37 in treated and control rats, resp., after 60 min of labeling, indicating that PE was incorporated into EPG without being hydrolyzed. After the longer incubation times (30-60 min), choline phosphoglycerides (CPG) were also found to be labeled, indicating that some EPG were methylated into choline compounds (at 60 min, about 20% of total lipid radioactivity in the liver was confined to (CPG). It is concluded that PE is taken up as such into liver cells and is incorporated into EA and CPG in both normal and ethanol-intoxicated rats.

7395 IN VIVO SIGNIFICANCE OF THE MICROSOMAL ETHANOL OXIDIZING SYSTEM (MEOS). (Eng.)

Khanna, J. M.; Kalant, H. (Dept. Pharmacology, Univ. Toronto, Toronto, Ontario M5S 1A8, Canada). *Adv. Exp. Med. Biol.* 85A:281-302; 1977.

Studies on the *in vivo* significance of the microsomal ethanol oxidizing system (MEOS) are reviewed. There were no significant differences between alcohol-naive rats treated with CCl_4 (which decreases MEOS activity) and controls in the disappearance rate of ethanol from the whole body or the blood, suggesting that MEOS does not play a significant role in ethanol metabolism *in vivo* in the naive rat. The results of tests using rats pretreated with phenobarbital or chlorcyclizine, inducers of drug metabolism, support this conclusion. In these tests MEOS activity was significantly increased, but there was no difference in the ethanol metabolism rate in treated rats. The chronic administration of ethanol in a high fat, adequate protein diet resulted in a significant increase in MEOS activity but had no effect when given with a high protein, low fat diet. However, chronic treatment of rats with either type of ethanol-containing diet resulted in a significant increase in ethanol metabolism, also indicating that changes in MEOS are not related to changes in ethanol metabolism. Determination of the cytoplasmic and mitochrondrial $NAD/NADH_2$ ratios in rats treated chronically with ethanol indicates that an adaptive increase in the mitochondrial reoxidation of NADH in the chronic alcohol-treated rat leads to an increase in the ethanol oxidation rate. There is a marked variability in the inductive effect of ethanol on drug metabolism. In some cases (meprobamate) there is an increase in inducibility after chronic ethanol treatment, while in others (pentobarbital) there is no effect. Studies of the acute interaction between ethanol and drugs suggest that ethanol modifies the conformation of the microsomal hemoprotein, impairing its ability to carry out the drug hydroxylation reaction. The rate of ethanol metabolism was independent of dose (0.5, 1.0, 2.0, and 4.0 g/kg, i.p.) but was inhibited 83%-92% in all dose groups by 4-methylpyrazole (2 mmol/kg). These studies fail to support the existence of a non-ADH-mediated pathway of ethanol elimination in the rat. It is concluded that changes in MEOS activity bear no consistent relationship to ethanol metabolism.

7396 LIVER MONOAMINE OXIDASE (MAO) IN LIVER HOMOGENATE OF MICE INFECTED WITH Schistosoma mansoni AND EFFECT OF CERTAIN THERAPEUTIC AGENTS. (Eng.)

Samad, M. M. A.; Guirgis, F. K.; Zeitoun, R.; El-Feki, R. F.; Awadalla, H. N. (Faculty Medicine, Alexandria Univ., Alexandria, Egypt) *Tropenmed. Parasitol.* 28(4):554-559; 1977.

To determine whether measurements of monoamine oxidase (MAO) activity can be useful in assessing the degree of liver fibrosis and its progression with time or its reversal after treatment in hepatosplenic schistosomiasis, MAO activity in liver homogenates of mice infected with *Schistosoma mansoni* was determined from the 2nd to the 14th week following infection. In control animals, MAO activity ranged from 3.96 ± 0.64 to 4.52 ± 0.39 U. In infected animals there was a sharp and significant increase in MAO activity during the 2nd and 3rd week after infection (6.20 ± 0.72 and 6.22 ± 0.25 U, resp., $p<0.01$). The enzyme activity began to decrease at the 6th week (3.94 ± 0.62 U) and reached 0.68 ± 0.22 U ($p<0.01$) at the 8th week after infection. By the 14th week, the level had risen again to 3.38 to 0.73 ($p<0.05$) but the percentage decrease was still significant when compared to the control. Animals were given four different treatment regimens and sacrificed 2 hr after drug administration and at the 1st, 3rd, and 8th days following treatment. Tartar emetic (30 mg/kg i.p. for 5 days) produced a nonsignificant increase in MAO activity in the infected mice, but caused no change in the normal group. Stibophen (300 mg/kg i.p. for 5 days), niridazol (50 mg/kg p.o. for 5 days), and hycanthone (35 mg/kg i.m.) all caused significant increases in MAO activity of infected mice ($p<0.01$ or $p<0.05$, $p<0.01$, and $p<0.01$, resp.). Stibophen and hycanthone caused no significant changes in liver MAO activity of normal mice; niridazole caused a transient but significant ($p<0.05$) increase in MAO activity at 3 hr after the last dose. The increase in the liver MAO activity of treated mice indicates that the livers of these mice are returning to normal and that the formation of new fibrous tissue has stopped. Measurement of MAO activity can be a useful index for the progression or regression of liver fibrosis in bilharzial hepatosplenomegaly.

7397 PORPHOBILINOGEN OXYGENASE INDUCTION BY 2-ALLYL-2-ISOPROPYLACETAMIDE TREATMENT.

(Eng.) Tomaro, M. L.; Frydman, R. B. (Faculdad de Farmacia y Bioquimica, Universidad de Buenos Aires Junin 956, Buenos Aires, Argentina). *FEBS Lett.* 84(1):29-32; 1977.

effect of 2-allyl-2-isopropylacetamide (AIA)
dinistration on 5-aminolevulinic acid synthetase
A-synthetase) and porphobilinogen-oxygenase
B-oxygenase) metabolism was studied in rats.
ale Wistar rats fasted for 24 hr received a s.c.
ection of AIA (250 mg/kg). ALA was present in
ne collected 24 hr after AIA administration, and
imum excretion occurred between 24 and 48 hr
er injection (120 ± 14 nmol). No ALA excretion
present between 48 and 72 hr. PBG was excreted
y between 24 and 48 hr (146 ± 11 nmol). Micro-
al PBG-oxygenase activity in the AIA-treated
s increased simultaneously with ALA and PBG ex-
tion and reached a maximum 48 hr after the AIA
atment. No significant difference in PBG-oxy-
ase activity between the control and the treated
s was found 74 hr after the AIA treatment. The
her values of ALA-synthetase activity were found
the livers excised 24 hr after the AIA treat-
t, while in those excised 48 hr after the treat-
t, the values were almost normal. To examine if
or PBG, or both together, are involved in the
erved PBG-oxygenase induction, they were admin-
ered to rats, and oxygenase activity was ex-
ned. Six-hour urine samples from rats treated
ALA (4, 8, and 12 mg/kg, s.c.) contained 90% of
the excreted ALA and PBG formed at expense of the
ected ALA, in a 7:10 ratio of ALA:PBG. No sig-
cant increase of PBG-oxygenase activity over
rol was detected in ALA-treated animals. When
(8 mg/kg) and PBG (4 mg/kg) were administered
ther, similar results were obtained. About 30%
he injected porphyrin precursors were recovered
he urine samples. These data suggest that the se-
tial induction of ALA-synthetase and PBG-oxygenase
t involve a metabolic response to the problem
xcessive PBG formation.

UDP-GLUCURONYLTRANSFERASE IN PERFUSED RAT LIVER AND IN MICROSOMES: V. STUDIES WITH RATS.

(Eng.) Bock, K. W.; Clausbruch, U. C.
)ttenwalder, H. (Inst. Pharmacology and Toxi-
gy, Univ. Gottingen, D-3400 Gottingen, W. Ger-
). *Biochem. Pharmacol.* 27(3):369-371; 1978.

xplore the consequences of altered enzyme con-
int for glucuronide synthesis by intact tissue,
hthol glucuronidation in perfused livers and in
 microsomes from Gunn rats was studied and com-
 with that in Wistar rats. The formation of
hthol glucuronide and sulfate was found to be
ar, and similar levels of 1-naphthol glucuro-
(0.2 µmol/g tissue) and of UDP-glucuronic acid
0.4 µmol/g tissue) were found in liver tissue
th strains at the end of the perfusion experi-
. The level of UDP-glucuronyltransferase
T) was markedly decreased in Gunn rat micro-
with and without activation (0.7 ± 0.1-14.6
nmol/min/mg protein) compared with Wistar rat
somes (1.5 ± 0.4-50.1 ± 9.7 nmol/min/mg pro-
. The solubilized Gunn-rat enzyme appeared
less stable upon storage than was the corres-
ng enzyme preparation from Wistar rats. These
ngs could be explained by assuming either a
tive enzyme and/or abnormal phospholipid en-
interactions in the Gunn rat with glucuronide
esis sustained by compensatory activation of
the latent enzyme. In both Gunn and Wistar rats, such activation was detected in the liver microsomes using bilirubin, but in perfused Wistar rat livers, 7 µmol of bilirubin caused no activation and 43 µmol decreased 1-naphthol glucuronide synthesis to about 70% of normal. UDPGT activity was markedly induced in the microsomes of Wistar rats by 3-methylcholanthrene (specific activity increased about fivefold), but Gunn rat microsomes were unresponsive. UDPGT activity was inducible to the same extent (about twofold) in both strains by phenobarbital. When morphine and chloramphenicol were used as substrates instead of 1-naphthol, microsomal UDPGT activity was similar in both Gunn and Wistar rats both in basal enzyme level (7 ± 2 and 1.0 ± 0.2 nmol/min/mg protein, resp.). These results support the hypothesis that the markedly decreased UDPGT activity (1-naphthol as substrate) in the Gunn rat does not lead to impaired glucuronide formation in perfused livers probably due to compensatory activation of the latent enzyme.

7399 REGULATION OF HEPATIC DRUG METABOLISM BY ELAIDIC AND LINOLEIC ACIDS IN RATS.

(Eng.) Hietanen, E.; Hanninen, O.; Laitinen, M.; Lang, M. (Dept. Physiology, Univ. Koupio, P.O. Box 138, SF-70101 Kuopio 10, Finland). *Enzyme* 23(2):127-134; 1978.

To elucidate the actual role of individual lipid components in the activation of hepatic drug metabolism, the effect of elaidic and linoleic acids on microsomal hydroxylation and glucuronidation reactions was studied in male Wistar rats. The rats were fed a fat-free diet and had elaidic or linoleic acid in doses of 40 and 200 mg/kg injected i.p. every other day for 4 weeks. The rats were then sacrificed and measurements, including body and liver weights and protein, phospholipid, and cholesterol contents of hepatic microsomes (native and trypsin-treated), were made. Pretreatment with either elaidic or linoleic acid altered the fatty acid composition of microsomal phospholipids and decreased the hepatic aryl hydrocarbon hydroxylase and *p*-nitroanisole O-demethylase (PNOD) activity in test rats compared with controls. The UDP-glucuronosyltransferase (UDP-GT) activity was lowered 20% by both acids at both doses compared with controls when *p*-nitrophenol was used as an aglycone; trypsin digestion did not reveal any latent changes in the UDP-GT activity. At the 40 mg/kg dose, linoleic acid-treated rats had significantly ($2p<0.01$) higher body weights than did controls. At 200 mg/kg of linoleic acid, a nearly significant ($2p<0.05$) decrease in body weight was noted. At the higher dose level, linoleic acid produced a nearly significant ($2p<0.05$) decrease in the amount of microsomal protein (both native and trypsin-treated). The activity of microsomal NADPH cytochrome c reductase and microsomal cytochrome P-450 contents were decreased by the higher dose of linoleic acid. Elaidic acid-treated rats had a slightly higher body weight than did controls, and the 200 mg/kg dose decreased the PNOD activity by about 60%, suggesting high sensitivity of this enzyme to elaidic acid. The experiments show that i.p.-administered fatty acids decrease the activities of mixed-function oxygenase enzymes as well as the UDP-GT activity, possibly by changing the phospholipid component in the microenvironment of membrane-bound enzymes. The changes are dependent on the fatty acid dose and may be enzyme specific.

7400 INHIBITION OF HEPATIC METABOLISM OF AZATHIOPRINE IN VIVO. (Eng.) Kaplowitz, N.; Kuhlenkamp, J. (Veterans Admin. Wadsworth Hosp. Center, Los Angeles, CA 90073). *Gastroenterology* 74(1):90-92; 1978.

To determine whether the hepatic thiolysis of azathioprine mediated by glutathione is enzymatic or nonenzymatic *in vivo*, the effects of probenecid (a glutathione *S*-transferase exogenous inhibitor) and of bilirubin (an endogenous inhibitor) on hepatic azathioprine metabolism were studied in rats. Male Sprague-Dawley rats received azathioprine (100 μmol/100 g) i.p. One group of rats received probenecid (50 μmol/100 g) at 30 and 5 min before azathioprine administration and the controls received saline. Male homozygous Gunn rats received azathioprine, and male Wistar rats served as controls. Azathioprine administration in the Sprague-Dawley rats resulted in 50% depletion of hepatic glutathione content at 5 min and in 80% depletion by 10 min. Probenecid pretreatment caused this depletion to decrease to 22% at 5 min and to 40% at 10 and 15 min ($p<0.001$ for azathioprine plus probenecid versus azathioprine alone at 5, 10, and 15 min). Less hepatic glutathione depletion was also found in hyperbilirubinemic Gunn rats; at 5 and 15 min, only 26% and 40% depletion of hepatic glutathione had occurred, whereas the levels in the controls were 50% and 80% at 5 and 15 min, resp. ($p<0.02$). The findings indicate that the conversion of azathioprine to 6-mercaptopurine *in vivo* is mediated enzymatically by the glutathione *S*-transferases.

7401 COLESTIPOL HYDROCHLORIDE, A NEW HYPOLIPIDEMIC DRUG: A TWO-YEAR STUDY--SUMMARY. (Eng.) Cooper, E. E.; Michel, A. M. (Santa Rosa Medical Center, San Antonio, TX). *Adv. Exp. Med. Biol.* 82:191-194; 1977.

The results of a 2-yr study on the potential use of colestipol hydrochloride as a hypolipemic drug are summarized. A randomized, placebo-controlled, single-blind study was carried out in 152 subjects, among whom 99 hyperlipemic (cholesterol >250 mg/100 ml) patients completed the 2-yr study. Within this group, 60 were treated with colestipol (5 g, t.i.d.), and the others were treated with placebo (Avicel). The serum cholesterol level decreased in the treated subjects from a pretreatment value of 300 mg/100 ml to 250 mg/100 ml after 1 month, to 267 mg/100 ml after 6 months, to 262 mg/100 ml after 1 yr, and to 279 mg/100 ml after 2 yr. The serum cholesterol level changed little in the 39 randomized placebo group. The drug caused no significant side-effects. It is concluded that colestipol hydrochloride effectively depresses cholesterol, but the hepatic synthesis of bile apparently compensates for the lowering of the total bile acid pool; therefore, no lithogenic milieu was produced.

7402 THE EFFECT OF DOPAMINE ON RENAL FUNCTION IN DOGS WITH CHRONIC LIGATION OF THE COMMON BILE DUCT. (Ger.) Benko, H.; Mostbeck, A. Peschl, L.; Schuller, J.; Neumayr, A. (I. Chirurgischen Universitatsklinik Wien, Vienna, Austria). *Wien. Klin. Wochenschr.* 89(16):562-566; 1977.

The effects of long-term (16-day) ligation of the common bile duct on the glomerular filtration rate (GFR), renal plasma flow (RPF), and urinary sodium excretion were studied in 12 male dogs during dopamine infusion (4 μg/kg/min). Administered before ligation, dopamine caused significant increases in GFR, RPF, and the urinary sodium excretion. Ligation without dopamine had no significant effect on GFR and RPF, but it slightly reduced the urinary sodium clearance. In the dogs with common bile duct ligation, dopamine had no significant effect on GFR and RPF, but it reduced the increase in the urinary sodium clearance from the 222.5% measured before ligation to 62.8%. The findings indicate the possible effectiveness of dopamine treatment in obstructive jaundice with renal failure.

7403 THE EFFECT OF FASTING ON GALACTOSAMINE INDUCED HEPATITIS IN EXPERIMENTAL ANIMAL (Eng.) Pickering, R. W. (Roussel Lab. Ltd., Kingfisher Drive, Covingham, Swindon, Wiltshire, England). *Arzneim. Forsch.* 27(10):1992-1996; 1977.

Because of the known alterations of metabolic processes during periods of fasting, the effect of fasting on galactosamine hepatitis was studied in male Sprague-Dawley rats and male hamsters fasted for 24 hr. The rats received 500, 1,000, or 1,500 mg/kg of galactosamine i.p. and the hamsters received 200, 400, or 800 mg/kg i.p. before or afte fasting in all cases. Liver damage was assessed by determining serum transaminase and liver glycogen levels. Fasting after galactosamine treatmen did not alter the course of liver injury in rats. Liver glycogen levels were significantly lower than normal after either fasting or galactosamine treatment alone (1,500 mg/kg) in rats ($p<0.05$) an after galactosamine treatment in hamsters. In ra fasted and treated with galactosamine, the liver glycogen content was significantly higher than that in controls ($p<0.05$). Fasting did not cause any alteration in the reduced liver glycogen leve in galactosamine-treated hamsters. Fasting cause no change in the SGOT or SGPT levels in untreated rats. Galactosamine (1,500 mg/kg) caused a significant increase in liver transaminase levels in nonfasted rats, whereas these levels were within normal limits in fasted rats. Galactosamine trea ment in unfasted hamsters caused increases in SGO and SGPT levels, whereas these increases were not seen in hamsters fasted 24 hr prior to galactosamine treatment. Galactosamine hepatitis is modi fied by previous fasting in rats and hamsters.

04 EFFECT OF GLUTATHIONE ON THE ACTIVITY
OF BILIRUBIN-BINDING PROTEINS FROM RAT
/ER CYTOSOL. (Eng.) Meuwissen, J. A. T. P.;
egers, M.; Srai, K. S.; Ketterer, B. (Dept. Medi-
l Res., Katholieke Universiteit Leuven, B-3000
ıven, Belgium). *Biochem. Soc. Trans.* 5(5):1404-
)7; 1977.

e hypothesis that reduced glutathione (GSH) is
quired to maintain the binding properties of
.irubin-binding proteins in the cytosol was tested
investigating the effects of GSH on the binding
bilirubin by protein components of rat liver
osol during a zone fractionation. Gel filtration
Gunn rat liver cytosol using Sephadex G-100
lded three bilirubin-containing fractions. The
st, eluted with the void volume, consisted either
colloidal bilirubin or of bilirubin associated
h small microsomal fragments. The second and
rd fractions coincided with ligandin and protein
resp. Total bilirubin recovery was only 50%, of
ch the largest part was found at the void volume.
gel filtration was carried out in a GSH-contain-
buffer, the recovery of bilirubin was complete;
e was found at the void volume, and the fraction
responding to ligandin contained 60-80% of the
ment. Gel filtration of mixtures of Gunn rat
er cytosol and Wistar rat plasma without the
ition of GSH, showed that protein A carried the
atest amount of total bilirubin, albumin less,
ligandin the least. In the presence of GSH,
andin bound the most bilirubin and albumin the
st. In neither system was bilirubin found at
void volume. These results show that the bind-
activity of the ligandin fraction for bilirubin
strongly influenced by GSH. The albumin and
protein A fractions might not be affected; if
s is so, they will carry comparatively more of
ligand because of competition with ligandin of
reased affinity. Cytosol proteins bind bili-
n more strongly than does albumin.

BIOTRANSFORMATION AND HEPATOTOXICITY OF
HALOTHANE. (Eng.) Brown, B. R.; Sipes,
. (Univ. Arizona Coll. Medicine, Tucson, AZ
1). *Biochem. Pharmacol.* 26(22):2091-2094; 1977.

rature concerning the mechanism of halothane
totoxicity is reviewed. Evidence from animal
riments suggests that the hepatic necrosis pro-
d by this anesthetic could be due to quali-
vely and/or quantitatively altered biotrans-
ation of halothane to reactive intermediates,
icularly via a reductive or oxygen-deficient
vay. Lipid peroxidation and extensive covalent
ing of halothane metabolites may occur, but may
fects, rather than causes. It is possible,
has not been proven, that these new substances
d induce a hypersensitivity phenomenon ac-
rating hepatic cellular destruction. Further
stigations into the precise mechanisms and
ation of halothane biotransformation should be
ied out.

REGULATION OF RAT ALPHA-FETOPROTEIN PRODUCTION BY METHIONINE AND ADENOSINE 5'-TRIPHOSPHATE. (Eng.) Watanabe, A.; Nagashima, H. (Okayama Univ. Medical Sch., 5-1, 2-chome, Shikata-cho, Okayama, Japan). *Res. Exp. Med.* 172(1):71-74; 1978.

Studies were carried out to determine whether a methionine-related metabolic event(s) is related to the repression of alpha fetoprotein (AFP) production seen after birth. The s.c. injection of methionine (2 mg/day) simultaneously with ATP (6.8 mg) and the injection of prednisolone (0.5 mg) both significantly accelerated the rapid fall of serum AFP concentration after birth ($p<0.025$ in both cases) in male and female Sprague-Dawley rats. Separate administration of methionine or ATP produced no similar effect. Serum and small intestinal extracts from adult rats showed similar effects on serum AFP levels, but the changes were not statistically significant. The half-life of AFP in methionine plus ATP-injected animals was almost the same as those in untreated controls, which may suggest that the administration of methionine plus ATP inhibits increased production of AFP or decreases the secretory rate of hepatic AFP into the circulation.

7407 THE METABOLIC EFFECTS OF SODIUM DICHLOROACETATE IN EXPERIMENTAL HEPATITIS IN THE RAT. (Eng.) Johnson, G. A. H.; Alberti, G. M. M. (General Hosp., Southampton SO9 4XY, England). *Biochem. Soc. Trans.* 5(5):1387-1389; 1977.

The hypolactatemic action of dichloroacetate was investigated in experimental liver disease. Liver damage was induced in rats by injecting galactosamine (1 g/kg) i.v. After a 24-hr fast, a basal arterial blood sample was taken, and NaCl (9 g/l, control) or dichloroacetate (300 mg/kg/hr) was infused for 120 min. Galactosamine administration resulted in a mild increase in the blood lactate concentration ($p<0.01$, as compared with that in untreated controls at 0-120 min), whereas the glucose concentration was unchanged. Blood lactate and glucose concentrations were decreased in galactosamine-treated animals, as compared with those in both the controls and those treated with galactosamine alone. For lactate, the differences were significant 30, 60, 90, and 120 min ($p<0.01$, 0.05, 0.01, and 0.01, resp.) when compared with the concentrations in the galactosamine-treated rats. The injection of fructose (1 g/kg, i.v.) in galactosamine-treated animals resulted in a marked increase in blood lactate concentration ($p<0.01$) at 15, 30, 60, and 90 min and in an increase in blood glucose concentration at 15 min ($p<0.01$), when compared with galactosamine-treated rats. The lactate concentrations in rats treated with galactosamine, fructose, or dichloroacetate were also significantly lower than those in rats treated with galactosamine alone ($p<0.01$) at 15-120 min, whereas the glucose concentrations were unaffected. The blood ketone body concentration was unaffected by galactosamine administration, increased by dichloroacetate infusion in galactosamine-treated rats, and decreased by fructose injection in galactosamine-treated rats. Dichloroacetate reverses galactosamine-induced hyperlactatemia and counteracts the effects of fructose infusion. The effects may be explained by activation of pyruvate dehydrogenase both extrahepatically and in the liver.

7408 COMPARISON OF BILIARY EXCRETORY FUNCTION AND BILE COMPOSITION IN MALE, FEMALE, AND LACTATING FEMALE RATS.

(Eng.) Klaassen, C. D.; Strom, S. C. (Univ. Kansas Medical Center, Kansas City, KS 66103). *Drug Metab. Dispos.* 6(2): 120-124; 1978.

The biliary excretion of four xenobiotic drugs that are not biotransformed before excretion was compared to determine whether there are differences in this excretion between male, female, and lactating female rats. The biliary excretion of i.v.-administered phenol-3,6-dibromphthalein disulfonate (DBSP, 100 mg/kg), ^{3}H-ouabain (4 mg/kg), indocyanine green (ICG, 10 mg/kg), and amaranth (200 mg/kg) was studied in Sprague-Dawley rats. The disappearance from the plasma of the four xenobiotics did not differ significantly in male and female rats. The cummulative biliary excretion of DBSP and ouabain was significantly greater ($p<0.05$) in the lactating females. However, the basal bile flow rate in the lactating females was about 50% higher ($p<0.05$) than in the males and nonlactating females. The increase in bile production decreased rapidly after removal of the pups from the dam. It was 74 ± 4 µl/min/kg on day 20 of gestation but only 42 ± 2 µl/min/kg 13 days after parturition. The concentration of phospholipids and cholesterol in the bile of the lactating females was significantly higher ($p<0.05$) than in the bile of the nonlactating females but was similar to that in the bile of the males. The increased bile flow in the lactating females appeared to be due to an increase in canalicular production, since the bile/plasma erythritol concentration ratios were similar in all three groups. Inasmuch as the bile salt concentration did not change in the bile, there appeared to be increases in both the bile salt-dependent and -independent fractions of bile. The increase was due to a more efficient liver rather than to a larger liver, as the weights of the livers (3.8% of body weight) were similar in all three groups.

7409 METABOLISM OF BILE ACIDS IV. ABSORPTION, DISTRIBUTION, EXCRETION, AND METABOLISM OF ORALLY ADMINISTERED URSODEOXYCHOLIC ACID IN RATS.

(Eng.) Ota, M.; Isobe, J.; Tsuji, Y.; Kuramoto, T.; Hoshita, T. (Hiroshima Univ. Sch. Medicine, Hiroshima, Japan). *Hiroshima J. Med. Sci.* 26(4):233-251; 1977.

The absorption, distribution, excretion, and metabolism of ^{14}C-labeled ursodeoxycholic acid (30 mg/kg p.o. or i.v. as a single dose or once daily for 21 days) in male and pregnant female Wistar rats were studied. The bile acid was absorbed rapidly (>70% within 2 hr) by passive diffusion (the time course was a straight line) and was distributed along with its metabolites only in the hepatobiliary system and gastrointestinal tract. The greater amount was in the latter site, suggesting that the main pool of ursodeoxycholic acid is in the small intestine. There was no accumulation of bile acid, which was excreted primarily in the feces with negligible amounts in the urine and respiratory CO_2. The half-life of ursodeoxycholic acid after a single p.o. dose was 2.3 days and after 21 p.o. doses was 1.5 days. There was a conspicuous transportation of the bile acid through the placenta with distribution in the fetal liver and intestine, but there was little secretion in the milk. The bile acid disappeared more rapidly from the fetus than from the maternal intestine. Ursodeoxycholic acid was converted to tauroursodeoxycholate in the liver, and the latter was partially converted to tauromuricholate. The conjugated bile acids, which represented >70% of the input radioactivity, were hydrolyzed to the corresponding free bile acids in the colon, and lithocholic acid and hyodeoxycholic acid were formed, resp., in the intestine as further metabolic products. The latter metabolites and muricholic acid were the major metabolites excreted in the feces. A metabolic scheme for ursodeoxycholic acid is presented; its metabolic fate closely resembles that of chenodeoxycholic acid except that fewer 6-hydroxylated metabolites are formed, suggesting that the liver enzymes responsible for metabolizing these two bile acids cannot metabolize them to the same extent.

7410 STUDIES ON LIPID METABOLISM IN RATS FED ON HIGH FAT AND HIGH CARBOHYDRATE DIETS WITH REFERENCE TO THE INDUCTION OF FATTY LIVER. PART I. BIOCHEMICAL OBSERVATIONS.

(Eng.) Sato, F.; Mizunuma, T. (Sch. Medicine, Tokushima Univ., Tokushima, Japan). *Tokushima J. Exp. Med.* 24(3/4): 95-104; 1977.

To learn whether the factors that control hepatic triglyceride synthesis contribute to the etiology of lipemia induced by carbohydrate and of fatty liv induced by fat, changes in enzyme systems concerned with triglyceride synthesis were studied in male Wistar rats given high carbohydrate or high fat die Disc-electrophoresis of serum lipoproteins showed t the very low density lipoprotein fraction was much greater in rats fed the carbohydrate diet than in rats fed the fat diet, the triglyceride and cholesterol levels being significantly increased in the latter group at several sampling times ($p<0.05$). This finding indicated that the increased liver lipid content of rats on the high fat diet was due mainly to increased triglyceride. The serum triglyceride level was significantly higher in the animals on the high carbohydrate diet (97 ± 9 mg/dl) than in those on the high fat diet (34 ± 5 mg/dl, $p<0.05$), as were the activities of glucokinase (20.1 ± 1.4 versus 11.0 ± 0.9 µmol/min, $p<0.05$) and acetyl-coenzyme A carboxylase (2.3 ± 0. versus 1.8 ± 0.1 µmol/min, $p<0.05$). The serum leve of ketone bodies and the activities of phosphoenolpyruvate carboxykinase, glycerol kinase, acyl-CoA synthetase, and diacylglycerol acyltransferase were significantly higher in the animals on the high fat diet than in those fed the high carbohydrate diet (1.49 ± 0.24 versus 0.84 ± 0.16 µmol/ml, 75.6 ± 4.6 versus 45.3 ± 3.4 µmol/min, 29.0 ± 1.7 versus 20.0 ± 2.1 µmol/min, 0.91 ± 0.04 versus 0.71 ± 0.05 µmol/min, and 1.76 ± 0.12 versus 1.24 ± 0.1 µmol/

resp., $p<0.05$ in all cases). The serum levels
holesterol, phospholipid, free fatty acid, and
ose; the activities of α-glycerophosphate de-
ogenase and cholinephosphotransferase; and the
rporation of ^{14}C-leucine into liver protein
similar in the two groups. These results sug-
that excess triglyceride formation over phos-
ipid formation might have an unfavorable effect
ipoprotein formation in rats on the high fat
or that triglyceride might be combined with
pholipid and secreted easily as lipoprotein in
on the high carbohydrate diet.

STUDIES ON LIPID METABOLISM IN RATS FED
ON HIGH FAT AND HIGH CARBOHYDRATE DIETS
REFERENCE TO THE INDUCTION OF FATTY LIVER.
II. ELECTRON MICROSCOPIC HISTOCHEMISTRY.
) Sato, F.; Mizunuma, T. (Sch. Medicine,
hima Univ., Tokushima, Japan). *Tokushima J.
Med.* 24(3/4):105-112; 1977.

ucidate the structural changes that occur
ver cells as the fat content increases,
elationship between the formation of fat
ets and abnormalities in the organelles
g the development of fatty liver was studied
ght and electron microscopy in male Wistar
fed a high fat or high carbohydrate diet.
24 hr of the high fat diet, numerous os-
ilic particles appeared in the hepatic cells
sinusoidal surface and in the Golgi appa-
adjacent to the space of Disse. After 72
rge (0.3-1.7 μm) lipid droplets without lim-
membranes were sometimes found in the cyto-
of liver cells, and they seemed gradually to
se in number and size. Characteristic changes
bservable by light microscopy after 3 and 7
of the high fat diet: large lipid droplets
ocated in the peripheral and intermediate
of the hepatic lobules, while a few small
ts were seen in the central area. After 3
there was a marked increase in the number
id droplets in the liver cells, and the rough
asmic reticulum had lost its lamellar con-
tion and was dilated and empty. After 7
many large lipid droplets with glucose-6-
atase reaction products adhering to their
es were seen in the cytoplasm, but the lipid
s and mitochondria had no detectable enzyme
y. The large lipid droplets may have been
by the fusion of smaller droplets. After
of the high carbohydrate diet, many gly-
ranules were seen between the mitochondria
oplasmic reticulum, but there were vir-
no lipid droplets. The data suggested that
rastructural changes in fatty liver result
e reduction of lipoprotein formation in the
smic reticulum, which is related to the re-
f triglyceride from the liver.

Intestine

436 ENTEROCYTE TURNOVER AND CONTENT IN FAT-FED HAMSTERS. (Eng.) Mansbach, C. M., II Veterans Admin. Hosp., 508 Fulton St., Durham, NC 7705). *Am. J. Dig. Dis.* 23(6):486-492; 1978.

o determine if a physiological basis exists for the ncrease in specific activities of cryptal lecithin-ynthesizing enzymes seen in hamsters fed a fat-upplemented diet, ^{3}H-thymidine incorporation, cel-ular migration rate, and mucosal concentration of NA, protein, and lecithin were measured. Radio-utographic studies showed that the labeling index nd cell migration rate throughout the intestine in he fat-fed hamsters and in the proximal three-uarters of the intestine of the control group were he same. Both parameters were reduced in the dis-al quarter of the control intestine in comparison ith the values in the hamsters fed the fat-supple-ented diet ($p<0.02$ and $p<0.01$, resp.). The protein/NA ratio was significantly increased in the prox-mal three-quarters (a 50% reduction in DNA con-ent) and modestly in the distal quarter of the ntestine of the fat-fed group as compared to con-rols, suggesting cellular hypertrophy. The leci-hin content of the proximal three-quarters of in-estine was the same in both groups but reduced n the distal quarter of the gut of the fat-fed roup ($p<0.0320$). These studies suggest that lipid eeding in the hamster can have profound effects on ntestinal cellular content and turnover.

437 PANCREATIC, GALLBLADDER, AND INTESTINAL RESPONSES TO INTRALUMINAL MAGNESIUM SALTS N MAN. (Eng.) Malagelada, J. R.; Holtermuller, . H.; McCall, J. T.; Go, V. L. W. (Mayo Clinic, 00 First St. SW, Rochester, MN 55901). *Am. J. Dig. is.* 23(6):481-485; 1978.

o investigate further the mechanisms of action of agnesium salts as laxatives and choleretics, an *n vivo* bioassay was used to quantify the effects f duodenal $MgSO_4$ or $MgCl_2$ on the release of chole-ystokinin (CCK) and to compare them with the effects f Ca or fatty acids previously studied under simi-ar conditions. The intraduodenal perfusion of a onabsorbable marker was used to measure pancreatic nzyme outputs in response to intraluminal stimuli, nd total bilirubin outputs and net jejunal fluid ovements were simultaneously quantified in 10 ealthy volunteers. Perfusions of both $MgSO_4$ and gCl_2 at concentrations >6 mM (12, 25, or 50 mM) ignificantly ($p<0.05$) increased trypsin output bove the saline control, and the 50 mM $MgSO_4$ and gCl_2 perfusions significantly ($p<0.05$) increased ilirubin output above the control. In neither ase was there any difference in effect between quimolar concentrations of the two Mg salts. The) mM $MgCl_2$ perfusion inhibited jejunal water ab-orption significantly compared with the saline ontrol ($p<0.01$); the 50 mM $MgSO_4$ perfusion was ore potent and induced a net water secretion when ompared with either the control ($p<0.01$) or the 50 mM $MgCl_2$ perfusion ($p<0.05$). These results demonstrate that magnesium salts exert a moderate stimulatory effect on pancreatic enzyme secretion and gallbladder contraction and that these actions are due to the Mg ion. However, much greater concentrations of Mg than of Ca or oleic acid (results of previous work) were required to exert this effect. Because the overall release of CCK depends on the length of bowel containing CCK-releasing cells that is exposed to a given stimulus, Mg is probably a weak stimulus to these cells or, alternatively, it triggers unidentified neurohormonal mechanisms that reduce its net CCK-like action. The actions of Mg salts on the digestive system are probably due to multiple mechanisms.

7438 ELECTRON IMMUNOHISTOCHEMICAL EVIDENCE FOR THE HUMAN INTESTINAL I CELL AS THE SOURCE OF CCK. (Eng.) Buchan, A. M. J.; Polak, J. M.; Solcia, E.; Capella, C.; Hudson, D.; Pearse, A. G. E. (Hammersmith Hosp., London W12 OHS, England). *Gut* 19(5):403-407; 1978.

Alternate semithin-thin serial sections for light and electron microscopy and antibodies to a synthetic fragment of the midpart of the cholecystokinin-pancreozymin (CCK-PZ) molecule (i.e., 9-20) that was free of cross-reacting subpopulations to gastrin were used to identify the cell source of CCK-PZ. Twenty-five surgical samples of human antrum, duodenum, and jejunum were examined. Scattered endocrine cells within the duodenal and jejunal mucosa were specifically stained by CCK-PZ (9-20), whereas the antrum failed to show any positive staining in the semithin sections. The CCK-PZ cells were then identified at the ultrastructural level on consecutive sections as a homogeneous population of cells with mainly round, sometimes angular, relatively dense granules averaging 260 ± 22 nm in size; the corrected value was 330 nm. I cells as identified by conventional electron microscopy also showed mainly round, compact granules with closely applied membrane, measuring 253 ± 58 nm in size; the corrected value was 322 nm. None of the cells reacting with the CCK-PZ (9-20) antibodies were G cells by conventional electron microscopy. The I cell is the source of CCK-PZ in humans.

7439 MOTILIN RELEASE IN THE PIG. (Eng.) Modlin, I. M.; Mitznegg, P.; Bloom, S. R. (Dept. Surgery, UCLA, Los Angeles, CA). *Gut* 19(5): 399-402; 1978.

Motilin release in the pig was investigated *in vivo* to clarify some of the species differences that seem to exist between the pig, the dog, and man. When 30 cm of distal duodenum and proximal small intestine were perfused with normal sodium chloride for 15 min, motilin levels in the portal vein and peripheral blood remained steady at 62 ± 10.6 pM and

54 ± 9.7 pM, resp. Following acid perfusion (0.1 M HCl at 1 ml/min), the plasma motilin concentration increased to a peak at 15 min of 111.2 ± 9.4 pM in the portal blood and 98 ± 8.6 pM in the peripheral blood, and these levels were maintained until the vascular pedicle of the perfused small bowel was clamped at 30 min. Despite continued perfusion with acid, the mean portal motilin level fell to 41 ± 4.8 pM and the mean peripheral blood motilin level to 38 ± 5.0 pM during clamping. When the vascular clamp was released after 20 min, the motilin level rose to a peak by 10 min (191 ± 23 pM in the portal blood and 180 ± 20 pM in the peripheral blood). Calculation of the disappearance half-time after clamping gave a value of 3.9 ± 0.2 min, with a good straight-line fit (r= 0.992). Ingestion of a 300-g meal did not significantly alter the fasting basal systemic plasma level of motilin (45 ± 6 pM) during a 75-min sampling period. Motilin release appears to be an entirely local phenomenon, and its physiological role remains speculative. It may play a role in mediating the motor response to lowered duodenal pH.

7440 EFFECTS OF HYPOPHYSECTOMY AND HYPOPHYSECTOMY PLUS GROWTH HORMONE ON SECRETIN RELEASE AND ON CONCENTRATIONS OF SECRETIN IN THE DUODENAL MUCOSA. (Eng.) Teichmann, R. K.; Schafmayer, A.; Hill, F. L. C.; Rayford, P. L.; Thompson, J. C. (Univ. Texas Medical Branch, Galveston, TX). *Surg. Forum* 28:375-376; 1977.

A study was carried out to test the effects of hypophysectomy (hypo-x) and hypo-x plus growth hormone (GH) on secretin levels in the blood and in the duodenum of the rat before and after duodenal perfusion with HCl. The 60 hypophysectomized Sprague-Dawley rats received either saline s.c. (30 controls) for 10 days or 25 μg GH s.c. for 10 days and were then tested along with 60 unoperated controls by infusion of HCl (0.1 N, 0.7 ml/min via a catheter) with sampling of blood and tissue prior to and at 5, 15, 30, and 60 min after infusion. The mean basal plasma secretin level was markedly lower in hypo-x rats (113 pg/ml) than in intact (134 pg/ml) or hypo-x plus GH rats (166 pg/ml). However, at 5 min, the hypo-x rats had markedly higher mean plasma secretin levels than did the intact or hypo-x plus GH rats (374, 251, and 285 pg/ml, resp.). All three groups showed a decrease in mean plasma secretin level after 60 min of irrigation with HCl (155, 176, and 181 pg/ml, resp.). Hypo-x rats had the highest mean basal secretin level in duodenal mucosal tissue (442 ng/g), whereas the intact and hypo-x plus GH rats had lower values that were similar to each other (229 and 242 ng/g, resp.). Continuous acid perfusion produced a stepwise depletion of mucosal secretin levels up to 30 min (100, 79, and 109 ng/g in hypo-x, intact, and hypo-x plus GH rats, resp.) with no further significant change by 60 min. The increased duodenal secretin stores may be responsible for the initial large secretin release in response to HCl seen in hypo-x rats. Because GH reverses these effects, the pituitary may play a role in the release and metabolism of secretin.

7441 IMMUNOHISTOCHEMICAL LOCALISATION OF UROGASTRONE TO HUMAN DUODENAL AND SUBMANDIBULAR GLANDS. (Eng.) Heitz, P. U.; Kasper, M.; Van Noorden, S.; Polak, J. M.; Gregory, H.; Pearse, A. G. E. (Dept. Pathology, Univ. Basel, Schonbeinstrasse 40, CH-4056 Basel, Switzerland). *Gut* 19(5):408-413; 1978.

To establish the precise localization of urogastrone in normal human tissues, immunostaining and improved cytochemical techniques were used on freeze-dried human tissue samples fixed in formaldehyde vapor. Fresh operative samples of tissue surrounding tumors of submandibular and parotid glands and kidney and operative and biopsy specimens from pancreas, corpus and antrum of stomach, duodenum, jejunum, ileum, and colon were examined. All tissues were normal by histological examination. The immunoreactive peptide gave positive granular immunostaining in the submandibular gland acini and the duodenal (Brunner's) gland acini and ducts. Cells of the duodenal glands had immunostaining localized to the supranuclear part of cytoplasm. Increased immunostaining was observed in the duct cells of duodenal glands with little or no staining of the duodenal crypt epithelium. The content of the ducts and part of the duodenal surface film also showed intense reaction. In the submandibular glands, the immunostain was confined to granules of some acinar cells. The duct cells did not show any reaction. Immunostaining observed in the pyloric glands was considered to be nonspecific. No immunostaining was seen in the other tissues tested. It is conceivable that urogastrone is a protective factor with a dual action: inhibition of gastric acid secretion and stimulation of cell proliferation or regeneration of the intestinal mucosa. Thus it may have both regulatory and protective functions and may be useful as a therapeutic agent.

GENERAL

APOPTOSIS IN THE SMALL INTESTINE OF ZINC-
DEFICIENT AND FASTED RATS. (Eng.) Elmes,
. (Univ. Hosp. Wales, Heath Park, Cardiff CF4
Wales). *J. Pathol.* 123(4):219-224; 1977.

idy was carried out to determine whether apop-
bodies (membrane-bounded bodies formed by
condensation and fragmentation of the cell dur-
cell death) occur in the small intestine of
during zinc deficiency. Forty-two Wistar-
ved albino rats were divided into zinc-deficient
with <1 ppm zinc), pair-fed control (4 ppm
supplement in diet), and *ad libitum*-fed con-
(11 ppm Zn^{2+} in diet) groups for 4-6 weeks;
emale Wistar rats were divided into 5 groups:
sted and 24, 48, 72, or 96-hr fasted rats.
tron microscopy revealed a few apoptotic bodies
ved from scattered single cells in the control
intestines (averages of 1.6, 3.25, and 3.1
otic bodies/5-µm section in the duodenum,
num, and ileum, resp.). The zinc-deficient
als showed severe signs of zinc deprivation;
-fed controls were underweight but fit and *ad*
tum-fed controls were healthy. While all ani-
had apoptotic bodies, these were too numerous
ount in the zinc-deficient rats. The number of
bodies was greatest in the duodenum and je-
and least in the ileum, with wide variations
animals; the bodies were present mainly in
idzone of the crypts. The number of apoptotic
es in the jejunum and ileum of fasted rats in-
sed with the length of the fast and were nu-
s in both the midzone and fundus of crypts
72 hr of fasting. The results demonstrate
apoptotic bodies occur normally in small num-
in the rat intestine and are markedly in-
sed in number during zinc starvation and fast-
It is suggested that the failure of DNA syn-
s that may occur during both zinc starvation
asting may increase the rate of cell death
optosis.

7450 REARING REGIMEN PRODUCING PIGLET DIARRHEA (ROTAVIRUS) AND ITS RELEVANCE TO ACUTE INFANTILE DIARRHEA. (Eng.) Lecce, J. G.; King, M. W.; Dorsey, W. E. (Dept. Animal Science, North Carolina State Univ., Raleigh, NC 27607). *Science* 199 (4330):776-778; 1978.

To develop a successful regimen for weaning and rearing excess piglets (those a sow cannot adequately nurse in a large litter) adaptable to existing farm conditions, several experiments were carried out. When 93 piglets farrowed on a commercial farm were taken after 1 day of nursing and reared over 1.5 months in an isolated nursery with an automatic feeding device (Autosow) to 2 weeks of age, 70% experienced vomiting and diarrhea after 1 week; 43/93 were treated with 25 ml cow colostrum (3 times/day for 5 days) and 7% died; 50/93 were not treated and 29% died. Weight gains in the survivors were only 2.5 instead of 3-4 times their birth weights. When piglets farrowed in a sanitary environment and nursed for 1 day were placed in a fresh nursery with new groups introduced every 10 days (producing continuous, overlapping use of the nursery), about seven litters were reared without incident to the expected 2-week weight gain over a 5-week period. Then a mild, transient diarrhea lasting <1 day occurred in the older pigs. Between 5 and 7 weeks of nursery use, the diarrhea became more pronounced, of longer duration, and affected more piglets; sometimes initial vomiting occurred, but there was no dehydration and no death. Between 7 and 9 weeks, all entering piglets began vomiting at 3-5 days of age, they underwent dehydration, the death rate was ≥50%, and the surviving piglets gained only 2.5 times their birth weights. After 9 weeks, all piglets began vomiting 2-4 days after entry and were dead by 10 days of age. Bacteria-free infectious material containing large numbers of rotavirus (about 10^9/ml) was obtained from diarrheal fluid.

The experiment was repeated for six successive cycles of the same description (the cycles were sometimes shorter but always showed the pattern of increasing severity) with a complete cleaning, fumigation, and 1-week period of vacancy between cycles. There was no correlation between the number of airborne bacteria (always 500-1,000/m^3) and either the length of continuous use of the nursery or the initiation of diarrhea. Antibodies to pig rotavirus were found in all samples of pooled cows' colostrum tested. Eighty-eight percent of 150 sows in 14 herds had antibodies to pig rotavirus that could be passed to their 1-day-old piglets via colostrum. It is concluded that, in the natural situation, the high prevalence of rotavirus assures that the neonate will first encounter it while passively protected by colostral antibodies and that an active immunity will issue from constant exposure without the burden of overt disease. However, the nursery contains susceptible piglets (those >1 day old and without colostral antibody) capable of amplifying the infection; with continuous use, an infection of increasing severity passes from young to young. Cleaning the delivery room to lower the initial viral dose, cleaning the nursery between groups to prevent amplification, and using p.o. antibody therapy can prevent the disease.

7451 A SIMPLE ENZYMATIC METHOD FOR ISOLATION OF HEPATOCYTES. (Eng.) Igarashi, S. (Tokyo Hosp., Japan Monopoly Corporation, 1-4-3 Mita, Minato-ku, Tokyo, Japan). *Experientia* 33 (10):1401-1402; 1977.

A new technique for the isolation of hepatocytes was developed. Liver was removed aseptically as a whole from Wistar rats, washed with physiological saline, injected (10 ml/min) with 20 ml of 0.05% bacterial collaginase in Ca-free Hank's solution (that was warmed in advance to 37 C) at one or more sites to produce a diffuse whitish color change of the whole liver, washed once in Ca-free Hank's solution, and then torn into small pieces with forceps in a dish containing 10-20 ml of the solution. Hepatocytes were liberated during this procedure. The tissue- and cell-containing solution was filtered through a 150-mesh platinum sieve and centrifuged at 200 rpm for 3 min. The sediment was suspended in 10 ml of Eagle's minimum essential medium (MEM) and centrifuged again for two cycles of purification to remove RBC. The recovery of hepatocytes was >90% of the amount of the initially isolated cells (average of 10 experiments was 7.86 ± 4.24 x 10^6 cells/g wet tissue). The contamination by mesenchymal cells was <1%. More than 95% of the isolated hepatocytes excluded trypan blue. The rate of glucose production from 2 μmol of alanine or lactate was 7.76 and 8.67 nmol/hr/10^6 cells for alanine and 16.33 and 10.87 nmol/hr/10^6 cells for lactate in two separate experiments. The new technique is simple, reduces the preparation time to 1/2-1/3 compared with hepatic perfusion methods, and lowers the risk of bacterial or fungal contamination during isolation.

DIAGNOSTIC PROCEDURES

7473 TRANSMUCOSAL POTENTIAL DIFFERENCE; DIAGNOSTIC VALUE IN GASTRO-OESOPHAGEAL REFLUX.

(Eng.) Khamis, B.; Kennedy, C.; Finucane, J.; Doyle, J. S. (Royal Coll. Surgeons in Ireland, St. Laurence's Hosp., Dublin 7, Ireland). *Gut* 19(5): 396-398; 1978.

Transmucosal potential difference (PD) was determined in 19 patients with symptoms of upper gastrointestinal disease, and the values were correlated with the histological appearance of mucosal biopsy specimens taken from the area of contact with the exploring electrode. PD in the lower esophagus was recorded at endoscopy, and suction biopsy specimens were obtained from the site of measurement and examined by light microscopy after hematoxylin and eosin staining. In 10 patients with normal histology, mean PD was -14.4 ± 0.4 mV, whereas in the 9 patients with histological changes of reflux, the mean was +9.4 ± 3.0 mV. In this latter group, polarity of the PD was reversed in all but one case. Good correlation ($p<0.001$) was found between these objective indices of lower esophageal disease and the presence of symptoms such as dysphagia and heartburn. The visual appearance at endoscopy was less reliable. It is suggested that measurement of PD is a simple, rapid, and sensitive method of detecting the presence of esophageal mucosal damage.

7474 ENDOSCOPIC TOLUIDINE BLUE SCATTERING METHOD IN THE DIAGNOSIS OF GASTRIC LESIONS.

(Eng.) Beker, S.; Eslava, F.; Zerpa, H.; Castillo, R.; Carballo, F.; Roa, E.; *et al.* (Apartado Postal 50794, Caracas, Venezuela). *Gastrointest. Endosc.* 24(2):72-73; 1977.

The efficacy of the direct application of toluidine blue to the gastric mucosa under immediate endoscopic observation in the diagnosis of gastric lesions was studied in 18 patients with normal stomach mucosae and 100 patients with gastric disease. The intensity of toluidine blue staining was graded from 0 (nonstained) to 4+ (deep royal blue staining). In 45 cases of gastritis without intestinal metaplasia, staining in the damaged mucosa was rated 1+ to 2+. In 16 cases of gastritis with intestinal metaplasia, toluidine blue stained between 2+ and 3+. In 17 gastric ulcers, staining was dark (3+ to 4+) at the base of the craters, but this was of no diagnostic value due to the presence of fibrin and to the healing process. The staining method was of value only when the dye appeared at the margins, where staining varied from 1+ to 2+; biopsy showed superficial gastritis and intestinal metaplasia. In 10 cases of scar formed after ulcer healing, 9 stained between 1+ and 2+, corresponding to the degree of gastritis. Of 12 patients with protuberant lesions, 6 were classified endoscopically as having benign polyps. In two polyps, with depressed centers, staining was 2+. In the other six protuberant lesions, endoscopically suspected as malignant, toluidine blue stained 4+, and the histologic diagnosis in all cases was adenocarcinoma. These results indicate that the endoscopic toluidine blue scattering method enhances the delineation of intestinal metaplasia and aids in the differential diagnosis of benign and malignant gastric ulceration.

7475 THE INFUSION SMALL-BOWEL STUDY. (Eng.)

Loewig, K. R.; Sanders, D. E.; Ho, C. S. (Toronto General Hosp., Toronto, Canada). *Appl. Radiol.* 6(6):100-101, 104, 151-152; 1977.

The value of intubation with rapid (80-100 ml/min) barium infusion into the fourth part of the duodenum was evaluated in roentgenology of 600 patients; five case reports are given briefly. Direct infusion has four major advantages over the conventional method that contribute to improved definition of morphology: (1) full distention to elucidate contour defects and distensibility, (2) double-contrast demonstration for intraluminal defects, (3) hypotonia for improved definition, and (4) fluoroscopy of the entire small bowel. The technique's use in diagnosing Crohn's disease, stenosis and ulceration that proved to be an area of ischemic enteritis, possible tuberculosis, and possible *Yersinia enterocolitica* infection is illustrated. The technique improves the threshold for recognition of subtle lesions and provides better detail for identification of specific disease processes.

7476 RADIONUCLIDE DIAGNOSIS OF BLEEDING MECK DIVERTICULUM IN CHILDREN.

(Eng.) Schu heim, A.; Moskowitz, G. W.; Levy, L. M. (Long Island Jewish-Hillside Medical Center, New Hyde Park, NY 11040). *Am. J. Gastroenterol.* 68(1):25-29; 1977.

The technique and results of ^{99m}Tc-pertechnetate scanning and computer analysis in 70 children with a suspected diagnosis of Meckel's diverticulum are presented. The patient is placed under the detector head of the scintillation camera so that some part of the stomach and the bladder is seen in the field of view. The videotape unit of the camera is starte just prior to the injection of the sodium pertech netate (0.15 mCi/kg, i.v.). The subsequent radio isotope distribution is visually monitored on the variable persistence oscilloscope and quantitativ recorded in digital mode for 60-90 min. Successi 4-min exposures are made at the exposure intensit that shows the general background activity as a slight haze, assuring that activities greater tha background are visible. At 45 min after the injection, the patient voids so that ectopic foci might not be obscured by the accumulating radioactivity of the bladder contents. Meckel's diverticulum usually visualizes early and generally simultaneously with gastric mucosa. A positive Meckel's diverticulum examination is the observation of a discrete localized collection of radioactive material separate from the stomach and bladder appearing generally in the right lower quadrant. When the results are equivocal, data manipulation on the Prime 300 general purpose minicomputer helps to differentiate Meckel's diverticulum from nonspecific collections of rad

vity. Five scans were positive in this ser-
and all were verified at surgery. None of the
ents with negative scans have been subsequently
d to have a diverticulum. The authors believe
this method is a safe procedure that should
onsidered a primary diagnostic modality in the
stigation of children with suspected bleeding
el's diverticulum.

EVALUATION OF ISCHEMIC BOWEL VIABILITY WITH A FLUORESCENT TECHNIQUE. (Eng.)

ar, C. J. H.; Randolph, J. G. (Abraham Lincoln
Medicine, 840 South Wood St., Chicago, IL
2). *J. Pediatr. Surg.* 13(3):221-225; 1978.

dy was carried out to develop objective cri-
for evaluation of small bowel viability fol-
g ischemia. The fluorescent pattern of is-
c rabbit intestine after the i.v. injection of
m fluorescein was correlated with a clinical
ation of intestinal viability in 45 female
ealand rabbits in which a 10-cm segment of
l ileum 15 cm proximal to the ileocecal valve
ubjected to ischemia for periods of 4-12 hr.
15 min of warming the ischemic segment, a
cal estimation of viability was made, 1 cm^3 of
dium fluorescein was injected, and the segment
graphed; a second-look operation was carried
4 hr later. All animals were supported with
mycin (3 mg/kg/day) and clindamycin (15 mg/kg/
begun preoperatively and continued for 10 days,
in (20 g/day, i.v.) until death or recovery,
ethasone (1 mg/kg, one dose), sodium bicar-
e, and Ringer's solution. All ischemic seg-
were studied grossly and histologically at
sy following death or sacrifice (at 6 weeks).
schemic segments (4-7 hr of ischemia) exhibited
mal pattern of fluorescence (bright green,
h, and evenly distributed in capillary beds)
f histology (exuberant mucosal villi and rela-
y thin serosa); all were predicted to survive
inical criteria, and all did. Three patterns
normal fluorescence were seen. Type I was
cterized by a diffuse reticular distribution
uorescence, indicating a diminished blood
y in the small vessels, and by interstitial
and mucosal loss, all of which reversed nearly
etely over the 6 weeks. Twelve segments (is-
c for 5-10 hr) showed this pattern; 7/12 were
cted to survive but 12/12 actually survived.
II was characterized by uneven dye distribu-
with large patchy areas of nonfluorescence,
he dye had disappeared completely 24 hr after
tion. Twenty-three segments (ischemic for 7-
) showed this pattern and fell into two groups.
A (15/23) showed interstitial edema, mucosal
hemorrhage, granulation tissue, and scarring;
was predicted to survive; 10/15 actually sur-
. Group B retained the initial dye, which
een after 24 hr in large confluent patches; a
t dye injection extravasated into the inter-
al spaces of the intestinal wall. Histo-
ally, there was complete autolysis. This group
eclassified as type III; all eight were not
cted to survive; all died. The fluorescent
d is much more reliable than conventional clinical predictors or survival following intestinal ischemia; the second-look procedure is a valuable part of the technique.

7478 THE USE OF GLUCAGON IN THE DIAGNOSIS AND MANAGEMENT OF ILEOCOLIC INTUSSUSCEPTION.

(Eng.) Hoy, G. R.; Dunbar, D.; Boles, E. T., Jr. (Ohio State Univ. Coll. Medicine, Columbus, OH). *J. Pediatr. Surg.* 12(6):939-944; 1977.

Experience with barium enema supplemented by glucagon in the diagnosis and treatment of 44 pediatric patients with suspected ileocolic intussusception is presented. Glucagon was given 5-20 min prior to the examination in a dose of 0.05 mg/kg either i.m. or i.v. Reduction of intussusception by the barium enema hydrostatic technique was accomplished in 21 of the 25 cases of intussusception. In 15 of the 21 patients, successful reduction was achieved on the first examination; in the other 6, it was achieved on the second examination. The second examinations were necessary because of mechanical problems in the apparatus or the catheter. Free reflux of barium into the terminal ileum was readily obtained in all these patients. The effect of glucagon on the comfort of the patient was assessed in 39 patients. Nineteen were completely cooperative and comfortable during the examination. Fourteen had some discomfort and were less cooperative, but the examination was not compromised. Only six patients were very uncomfortable and uncooperative. No serious complications or adverse reactions occurred in any patient. The use of glucagon in barium enema examinations seems to enhance the comfort of the patient and the ease of colon and small bowel filling.

7479 THE USE OF PRONE FILMS FOR SUSPECTED BOWEL OBSTRUCTION IN INFANTS AND CHILDREN.

(Eng.) Lorenzo, R. L.; Harolds, J. A. (Medical Univ. South Carolina, 80 Barre St., Charleston, SC 29401). *Am. J. Roentgenol.* 129(4):617-622; 1977.

The value of prone films of the abdomen, both frontal and cross-table lateral, in the differentiation of obstructive versus nonobstructive ileus is illustrated by six case reports of infants and children. In two cases, supine and upright films showed evidence of obstruction; however, prone and cross-table lateral films in the first case and prone films in the second demonstrated a normal amount of air in the rectum and excluded intestinal obstruction. In three other patients, in whom the supine and upright films showed distended bowel loops and air-fluid levels, the prone and/or cross-table lateral films showed no air in the rectum, thus suggesting obstruction. Meconium ileus, stricture secondary to necrotizing enterocolitis, and ileus secondary to a left inguinal hernia were subsequently diagnosed in these patients. In the remaining patient, the plain supine and upright views demonstrated distended bowel loops and air-fluid levels. A prone film showed air in a rectum of abnormal caliber, and a plain film diagnosis of low segment aganglionic megacolon was made. Barium enema and the findings at surgery confirmed this diagnosis. These observations show that prone and lateral decubitus films are useful in evaluating the gas in the large bowel, particularly in the rectum. The level of obstruction, as well as differentiation between obstructive and nonobstructive ileus, can be determined by this plain-film approach.

7480 PANCREATIC ENZYMES IN HUMAN DUODENAL JUICE--A COMPARISON OF RESPONSES IN SECRETIN PANCREOZYMIN AND LUNDH BORGSTROM TESTS.

(Eng.) Braganza, J. M.; Herman, K.; Hine, P.; Kay, G.; Sandle, G. I. (Manchester Royal Infirmary, Manchester, England). *Gut* 19(5):358-366; 1978.

The concentrations and total outputs of trypsin, amylase, and lipase secreted into the duodenum during secretin pancreozymin and Lundh Borgstrom tests were assessed in 12 patients without pancreatic disease and 3 normal subjects to assess the relative intensity of pancreatic stimulation provided by these means. The mean concentration of trypsin and the mean 10-min total output of trypsin, amylase, and lipase after the meal (though less than the peak postprandial responses) were equal to the respective peak enzyme responses after the i.v. injection of 2 Crick Harper Raper U/kg of secretin Boots and after the i.v. injection of 2 Crick Harper Raper U/kg of pancreozymin Boots.

7481 THE USE OF PROSTAGLANDIN F2-ALPHA IN SELECTIVE PANCREATIC AND LEFT GASTRIC ANGIOGRAPHY.

(Eng.) Legge, D. (Mater Misericordiae Hosp., Dublin, Ireland). *Clin. Radiol.* 29(3):285-288; 1978.

Prostaglandin F_2-alpha was used in 10 superselective angiographic studies of the pancreas for suspected carcinoma and 10 left gastric studies for suspected portal hypertension to improve anatomic detail and diagnostic accuracy. The injection of prostaglandin (60 μg) into the dorsal pancreatic or gastroduodenal artery increased opacification of small pancreatic vessels and better demonstrated the angiographic changes in all three patients who were found to have carcinoma of the pancreas. Injection of the drug into the left gastric artery increased opacification of the left gastric vein, allowed identification of the direction of flow of the contrast medium, and enhanced demonstration of gastroesophageal varices in the five patients in whom these were present. It is concluded that prostaglandin improves the quality of pancreatic and left gastric angiographic studies.

7482 ENDOSCOPIC ASPIRATION BIOPSY OF THE PANCREAS.

(Eng.) Tsuchiya, R.; Henmi, T.; Kondo, N.; Akashi, M.; Harada, N. (Nagasaki Univ. Sch. Medicine 7-1, Sakamoto-Machi, Nagasaki City, Nagasaki, Japan). *Gastroenterology* 73(5):1050-1052; 1977.

The diagnostic accuracy of endoscopic aspiration biopsy in malignancies of the periampullary region and the pancreas was assessed retrospectively in 51 patients. Biopsy is carried out with a side-viewing duodenal or gastric fiberscope and a newly designed biopsy needle. The needle consists of a guide tube and an inner tube made of Teflon. The guide tube for the gastrofiberscope is 1,542 mm long, and that for the duodenofiberscope is 1,790 mm. A 7-mm long 23-gauge metal needle is used for the gastrofiberscope, and a 6-mm long 26-gauge needle for the duodenofiberscope. Malignant cells were identified in 21 of 25 patients with carcinoma, making the overall diagnostic accuracy 84.0%. Malignant cells were diagnosed in 8 of 10 patients with pancreatic malignancy who underwent transduodenal aspiration biopsy, but not gastric biopsy. The false-negative diagnoses were made in patients with carcinoma of the body and tail of the pancreas. Malignancy was diagnosed in 10 of the 11 patients with cancer who underwent transgastric aspiration biopsy alone. In the patient in whom the correct diagnosis was missed, well-differentiated adenocarcinoma cells were thought to be benign atypical cells. Pancreatic carcinoma was correctly diagnosed in all four patients who underwent both gastric and duodenal biopsy. There were no false-positive diagnoses, and no complications attributed to the procedure were encountered. Endoscopic aspiration biopsy is valuable in the diagnosis of pancreatic carcinoma.

7483 CYSTIC FIBROSIS SCREENING IN THE NEWBORN

(Eng.) Crossley, J. R.; Berryman, C. C. Elliott, R. B. (Sch. Medicine, Univ. Auckland, 85 Park Rd., Auckland 3, New Zealand). *Lancet* 2(8048 1093-1095; 1977.

An improved colorimetric method for trypsin assay in stool samples as a test for cystic fibrosis in newborns is described, and the results of the method in consecutive neonates are reported. A colorless substrate, benzoyl-arginine-*p*-nitroanilide (BAPNA), releases yellow *p*-nitroaniline when hydrolyzed by trypsin. Stool samples from infant with cystic fibrosis, who lack trypsin, give negligible color. Among 4,500 newborns screened by this method, 2 were found to have cystic fibrosis. The method was also tested in five other untreate children known to have the disease, and the solutions had no yellow tint whatever. In 2,500 consecutive samples in which D,L-BAPNA was used as substrate, the frequency of positive results afte a single assay was 3.2%. Reassay of these sample gave a second specimen-request rate of 30/2,500. When the second specimens were assayed, 27 gave normal results, but 3 showed low enzyme activity. By quantitative assay of a stool specimen, one of these babies was shown to have normal enzyme activity, but that the other two had no enzyme activity. The diagnosis of cystic fibrosi was confirmed by a sweat test. When 13 consecutive specimens that had twice given false-positiv results (no color) with D,L-BAPNA (0.5 mg/test) were assayed with L-BAPNA (0.25 mg and 0.5 mg/tes 11 of 13 and 12 of 13, resp., gave normal results The authors are now screening with 0.25 mg L-BAPN test and reassaying with 0.25 mg and 0.5 mg/test; the frequency of positive results is now 0.4% aft

ne assay, reducing to 0.1% after reassay of the
ame specimen (2,000 samples). There has been no
vidence of false-negative results.

84 PANCREATIC INJURY FOLLOWING ERCP: FAILURE OF PROPHYLACTIC BENEFIT OF TRASYLOL.

Eng.) Brust, R.; Thomson, A. B. R.; Wensel, R. H.;
nerbaniuk, R. W.; Costopoulos, L. (Univ. Alberta
osp., Edmonton, Alberta, Canada). *Gastrointest.
ndosc.* 24(2):77-79; 1977.

ne value of Trasylol in the prevention of pancrea-
itis following endoscopic retrograde cholangio-
ancreatography (ERCP) was tested in 61 patients
n a double-blind randomized study. Postprocedural
yperamylasemia occurred in 66% of cases within 2
r, and in 57% the elevations in amylase persisted
or 24 hr after the procedure. Elevated urinary
mylase levels were found in 34% of patients. Symp-
oms attributable to the procedure occurred in 39%.
ne frequency of clinical and biochemical changes
as unrelated to the duration of the procedure (10
in-3 hr), the number of ducts cannulated, or ab-
ormalities in the ducts. The administration of
rasylol (200,000 U, i.v.) 2 hr before and 6, 12,
8, and 24 hr following ERCP failed to prevent or
ignificantly reduce the frequency or magnitude of
levations in serum or urine amylase activity or
o prevent postexamination abdominal pain.

85 THE USE OF PROSTAGLANDIN E_1 FOR ENHANCED VISUALIZATION OF THE SPLANCHNIC CIRCULA-

ON. (Eng.) Jonsson, K.; Wallace, S.; Jacobson,
D.; Anderson, J. H.; Zornoza, J.; Granmayeh, M.
. D. Anderson Hosp. Tumor Inst., Houston, TX
030). *Radiology* 125(2):373-378; 1977.

inical experience with prostaglandin E_1 (PGE_1)
an aid in enhancing portal vein visualization
d its use in angiography of the liver and pan-
eas are reported. When a single bolus injection
PGE_1 (5-7.5 µg except for 2.5 µg in a 5-yr-old
ild) was given into the superior mesenteric ar-
ry (SMA), hepatic artery (HA), or dorsal pan-
eatic artery (DPA) in 22 patients, the normal
jection rates for contrast medium were increased
mewhat, but the pain and sensation of heat ac-
mpanying this injection were identical to the
se without PGE_1. PGE_1 injection itself did not
oduce discomfort or significant pulse rate or
terial blood pressure changes in the patients.
E_1 injection dilated the arteries slightly and
rkedly increased blood flow; less reflux of
ntrast medium into adjacent arteries was noted.
e quality of portal vein opacification was greatly
proved in all patients in whom the comparison
s made: initial and optimal opacification oc-
rred at a mean of 5 and 10 sec, resp., with PGE_1
d 13 and 19 sec, resp., without PGE_1. The in-
eased injection rate (14 ml/sec for 3 sec) gave
ditional information in one hepatic angiogram
which a hypervascular metastatic lesion was
monstrated. In another patient, the injection of
E_1 and contrast medium (6 ml/sec for 5 sec) into
e DPA demonstrated a tumor in the tail of the
ncreas as a filling defect. In seven patients,
the parenchymal staining of the liver after SMA injection of PGE_1 and contrast medium showed filling defects corresponding to metastases or primary tumor in the liver. The use of PGE_1 markedly improves venous filling in splanchnic angiography.

7486 RESULTS OF TRANSJUGULAR ANTEGRADE CHOLANGIOGRAPHY AND RETROGRADE PORTOGRAPHY.

(Ger.) Thelen, M.; Paquet, K. J.; Schulz, D.; Herpertz, C. (Radiologische Klinik, Universitat Bonn, Bonn, W. Germany). *Roentgenblaetter* 30(10):508-519; 1977.

Transjugular antegrade cholangiography, liver biopsy, and retrograde portography are described. Transjugular cholangiography is indicated in intrahepatic or extrahepatic flow obstruction if i.v. or infusion cholangiography or endoscopic retrograde cholangiography are unsuccessful or unfeasible. Transjugular cholangiography was performed in 19 patients; it was successful in 16: stricture of a hepatojejunostomy was diagnosed in 5 cases, stricture of bile duct in 2, carcinoma of the common or hepatic bile ducts in 4, and iatrogenic stricture of the hepatic duct, stricture of the papilla, liver cirrhosis, chronic pancreatitis with stricture of the common bile duct, and compression of the hepatic duct by lymph node in 1 case each. Complication (injection under the hepatic capsule) occurred in one case only. Transjugular liver biopsy is indicated if transcutaneous biopsy or laparoscopy are unfeasible, and it is contraindicated (as is transjugular cholangiography) in hepatic echinococcosis, large liver abscess, and acute cholangitis. It was performed in 17 patients, and it was successful in 15. Hepatitis was diagnosed in two cases, liver carcinoma in one, liver fibrosis in six, liver cirrhosis in three, and cholestasis in three. Transjugular retrograde portography was performed in 41 patients with the clinical picture of liver fibrosis (4 cases), liver cirrhosis (25 cases), and intrahepatic space-occupying process (12). Liver cirrhosis with portal hypertension was diagnosed by transjugular portography in 29 cases, liver fibrosis in 4, echinococcosis in 3, and liver carcinoma in 5.

7487 PERITONEOSCOPY FOR THE DIAGNOSIS OF LEFT LOBE LESIONS OF THE LIVER.

(Eng.) Whitcomb, F. F., Jr.; Gibb, S. P.; Boyce, H. W., Jr. (Lahey Clinic Foundation, 605 Commonwealth Ave., Boston, MA 02215). *Arch. Intern. Med.* 138(1): 126-127; 1978.

The effectiveness of peritoneoscopy and direct vision liver biopsy were evaluated in 38 selected patients with focal lesions that had been detected by liver scan and were located predominantly in the left lobe or in the left portion of the right lobe where percutaneous blind biopsy was negative or nondiagnostic. ^{99m}Tc-sulfur colloid scans were performed because of hepatomegaly or abnormal liver function test results or both. Peritoneoscopy was successful in establishing the diagnosis in 36 of the 38 patients. The failures were due to uncooperativeness in one case and to adhesions from a previous operation that obscured the visibility in the other. Of the 36 patients, 30 had metastases that were clearly visible, 2 had Hodgkin's disease, 2 had thin left lobes, and 1 each had postnecrotic cirrhosis and polycystic disease. Two major complications were encountered: one patient had a decrease of hematocrit and required two transfusions although excessive bleeding had not been apparent immediately after the biopsy and another patient with Hodgkin's disease had postoperative fever and ileus (believed to be secondary to localized perforation of the bowel and peritonitis) that responded to antibiotics and i.v. fluids. Peritoneoscopy and direct vision liver biopsy are simple, safe, and accurate methods for the documentation of focal lesions involving predominantly the left lobe or the left portion of the right lobe of the liver.

7488 IMPROVEMENT IN VISUALIZATION OF HEPATIC LESIONS WITH UPRIGHT VIEWS. (Eng.) Mettler, F. A.; Shea, W. H., Jr.; Guiberteau, M. J.; Potsaid, M. S. (Cancer Res. Treatment Center, Univ. New Mexico, Albuquerque, NM 87131). *J. Nucl. Med.* 18(11):1128-1130; 1977.

To improve radiocolloid images of the liver by reducing the liver respiratory excursions, standing scintiphoto views of the liver were compared with conventional supine scans by a computer technique that was used to analyze and display the results. Patients and healthy volunteers were given 4 mCi of ^{99m}Tc sulfur colloid and scanned in both positions. In one patient with known hepatic metastases from lymphoma, the standard supine anteroposterior (AP) views alone would have resulted in a normal interpretation of the radionuclide scan, whereas the upright AP views were diagnostic (both views were considered along with gray-scale sonograms taken in each position the same day). Computer analysis of radiocolloid activity in the horizontal and vertical axes centered on a particular defect in a patient with known hepatic metastases from colon carcinoma demonstrated that the standing view gave better delineation of the lesion than did the supine view. Computer analysis of end-inspiration and end-expiration scans performed on normal volunteers showed that respiratory motion of the liver is approximately equal (2 cm) in the supine, prone, and sitting positions but is markedly decreased (0.5 cm) in the standing position. The standing position should be employed whenever maximal sensitivity for small focal defects is desired.

7489 EVALUATION OF BILIARY TRACT DISEASE BY DIAGNOSTIC ULTRASOUND. (Eng.) Lawson, T. L. (George Washington Univ. Medical Center, 901 23 St., NW, Washington, DC 20037). *Am. J. Dig. Dis.* 22(9):820-828; 1977.

The diagnosis of cholelithiasis and of biliary obstruction using ultrasound is reviewed. Gallstones produce three basic ultrasonographic appearances: focal, linear, or diffuse internal echoes; gallbladder wall contour irregularities of increased sonic density; and sonic shadowing. Focal inter
echoes are usually caused by large gallstones
(>0.5-1 cm diameter). Smaller, multiple gall-
stones may layer and float in the bile, giving a
linear area of sonic density with the gallbladde
If aggregates of small gallstones sink to the de
pendent wall of the gallbladder, they are seen a
an area of gallbladder wall irregularity of in-
creased sonic density. Sonic shadows are not se
in every case of cholelithiasis, but when shadow
ing occurs in conjunction with internal echoes o
contour irregularities, diagnostic confidence is
increased. Sonic shadowing from stones is usual
focal when seen in both longitudinal (sagittal)
and transverse scans; this shadowing can be dis-
tinguished from that produced by gas or barium
within the hepatic flexure, because the latter
usually more diffuse. Cholecystosonography is
reliable, with an overall accuracy of approximat
90%, a low composite false-positive rate of abou
1 or 2%, and a false-negative rate of approximat
5-10%. Dilated bile ducts can be visualized by
ultrasonography and usually appear as reticular
branching sonolucencies within the liver parench
Dilated bile ducts can be differentiated from he
patic veins, because hepatic veins become less
prominent in the periphery and most prominent as
they enter the vena cava in the region of the r
atrium. When dilated bile ducts are seen, the
diagnosis of extrahepatic biliary obstruction ca
be made with the exception of the unusual cir-
cumstance where there has been previous biliary
disease and persistent postoperative dilation.
Gallbladder diameter is not a good or reliable
sign of extrahepatic biliary obstruction becaus
of the great variabilities of gallbladder diame
in both diseased and normal conditions. Nevert
less, in the proper clinical setting, a gallbla
diameter of 4 cm or greater usually indicates p
ologic gallbladder dilation and biliary obstruc

GASTROINTESTINAL DISEASES

ESOPHAGUS

7503 RADIOLOGIC SPECTRUM OF OPPORTUNISTIC INFECTIONS OF THE UPPER GASTROINTESTINAL TRACT.

(Eng.) Athey, P. A.; Goldstein, H. M.; Dodd, G. D. (M. D. Anderson Hosp. and Tumor Inst., Houston, TX 77030). *Am. J. Roentgenol.* 129(3):419-424; 1977.

The pathogenesis, clinical aspects, pathologic findings, and radiologic features in 34 patients with opportunistic infections of the esophagus and/or stomach are discussed. Most patients had hematologic disorders, with leukemia the underlying diagnosis in 19 patients. Most had more than one predisposing factor, since virtually all were receiving some form of chemotherapy, corticosteroids, and/or antibiotics. Only one patient, who had gastric candidiasis, had no known predisposing factors. The most common presenting symptoms were dysphagia and/or substernal pain or burning. Because of the debilitated clinical state of the patients, the diagnosis of opportunistic infection was often based solely on clinical findings and radiologic examination, and in only a few was an organism actually cultured. In approximately half the patients, *Candida albicans* was cultured from the oropharynx, urine, and/or blood. In two additional patients, there was evidence of a *Klebsiella* infection. Abnormal esophageal motility was the most common radiologic finding and was present in 33 patients with esophagitis. Abnormal motility was the sole initial finding with no morphologic abnormalities in only two patients. The majority of cases demonstrated a slightly dilated, virtually atonic esophagus. In most instances, the morphologic changes involved the entire thoracic esophagus, although in approximately one-third of the cases, the proximal half was relatively spared even when oropharyngeal manifestations were present. A shaggy marginal contour was observed radiologically in most cases of opportunistic esophagitis. Thickening and irregularity of the mucosal folds, simulating the appearance of varices, reflected the severity of the inflammatory changes. A continuing severe inflammatory reaction lead to frank stricture in one patient. Two patients demonstrated the unusual finding of one or several large nodular filling defects in the esophagus representing "fungus balls" due to candidiasis. Two patients had gastric monilial infection, and in one, the "fungus ball" appearance was noted in the esophagus, stomach, and duodenum. Both patients were seen radiologically to have several raised nodular lesions scattered about the stomach, and most nodules had central ulcerations giving the target appearance.

7504 GASTRIC EMPTYING IN PATIENTS WITH REFLUX ESOPHAGITIS OR BENIGN STRICTURES OF THE ESOPHAGUS SECONDARY TO REFLUX COMPARED TO CONTROLS.

(Eng.) Csendes, A.; Henriquez, A. (Hosp. J. J. Aguirre, Univ. Chile, Santiago, Chile). *Scand. J. Gastroenterol.* 13(2):205-207; 1978.

To elucidate the pathogenesis of reflux esophagitis, gastric emptying of liquids was measured in 12 patients with reflux esophagitis, 7 patients with benign esophageal strictures secondary to reflux, and 11 healthy controls. Lower esophageal sphincter pressure and gastric pH were simultaneously determined as well. The solutions used were phenol red (30 mg/1) in 150 mM NaCl (solution A), phenol red (500 mg/1) in 150 mM NaCl (solution B), and 150 mM NaCl (solution C) and were given by intubation after a 12-hr fast. The stomach was fully emptied by aspiration, 750 ml of solution A was instilled over 1-3 min, an 8-ml sample was taken at 10 min, 20 ml of solution B was added and vigorously mixed for 45 sec, and a second sample was taken. A similar procedure was followed at 20, 30, 45, 60, and 90 min using 15, 10, 10, 10, and 5 ml of solution B, resp. At 120 min, a sampl was taken, 200 ml of solution C were added for 45 sec, and a final sample taken. No significant differences were found among the test groups with respect to half-time of gastric emptying, although there was a slight tendency toward slower emptying in the patients with benign strictures. There we also no significant differences among the test groups with respect to gastric emptying time (<10 of the instilled volume remaining in the stomach) or with respect to the emptying curve (the volume of instilled solution remaining at the various sampling time points). Gastric retention does no appear to be an important factor in the productio either of reflux or of strictures.

7505 ASSOCIATION OF ASPIRIN INGESTION WITH SYMPTOMATIC ESOPHAGEAL HIATUS HERNIA.

(Eng.) Smith, V. M. (301 Saint Paul Place, Baltimore, MD 21202). *South. Med. J.* 71(Suppl. 1):45- 1978.

Radiographic studies were carried out to test the hypothesis that esophagitis in patients with hiat hernia can be caused by delays in the passage of gested aspirin from mouth to stomach. Barium-fil pouches of esophageal hiatal hernia were shown to trap barium above the diaphragm for prolonged per ods despite repeated swallows of water or additio barium suspension. Swallowed barium sulfate tabl were shown to pass through the esophagus into the stomach within seconds in normal subjects. In patients with esophageal hiatal hernia, however, tablets frequently remained within the esophagus, sometimes shifting up and down within the esophag for prolonged periods before entering the stomach. In other patients, the tablets stayed at the esop gogastric junction for the entire observation per of 5 to 15 min before entering the stomach. In a other experiment, a 5-g aspirin tablet placed in buccal space below the lower central incisor teet for 15 min produced a slightly raised lesion. Le ing a tablet in place for 2 hr resulted in the development of an area of intense erythema and fri-

ity. Eighteen hours later, the gingiva in the
displayed erythema, edema, and friability, de-
trating that aspirin can corrode alkaline mucosa
he absence of acid.

STOMACH

PYLORIC ANTRAL MUCOSAL WEBS. (Eng.)
Feliciano, D. V.; van Heerden, J. A. (Mayo
ate Sch. Medicine, Univ. Minnesota, Rochester,
Mayo Clin. Proc. 52(10):650-653; 1977.

The current literature on pyloric antral mucosal webs is reviewed, and the symptoms, treatment, and results of treatment of seven patients are presented. The incidence of this defect is low. It is unknown whether it is congenital or acquired. The small series presented contributes little to resolving this controversy; however, three cases had documented normal gastric roentgenograms with subsequent appearance of the antral webs on more recent roentgenograms. The presenting features in infants include persistent postprandial non-bile stained vomiting and secondary failure to thrive. Adults present with postprandial fullness and/or epigastric pain, with relief by vomiting. Standard gastric roentgenograms with barium reveal thin, constant septa or bands about 1-2 cm proximal to the pyloric ring seen as radiolucent lines projecting into the center of the antral lumen from the greater and lesser curvatures of the prepyloric antrum. Other antral-pyloric lesions that must be distinguished from antral webs include redundant gastric mucosa, hypertrophic gastric rugae, distal gastrospasm, cholecystogastrocolic bands, cicatricial post-ulcer scarring, and heterotopic pancreatic tissue. Antral webs may be difficult to visualize endoscopically, as in one of the presented cases in which two separate procedures were required. The endoscope can usually pass down to, and occasionally through, the central aperture of the diaphragm into the pyloric channel. Lysis of the web together with gastroplasty resulted in cure in the three patients in whom these procedures were performed, and finger fracture of the web together with pyloromyotomy and removal of ectopic pancreatic tissue were successful in a fourth. The other three patients in the series were asymptomatic and received no treatment. Surgical treatment is recommended for patients with obstruction.

7522 MULTIPLE BIOGENIC AMINE-SECRETING 'CARCINOID' TUMOUR OF THE STOMACH: A CASE REPORT.

(Eng.) Bader, L. V.; Lykke, A. W. J.; Hinterberger, H. (St. George Hosp., Kogarah 2217, New South Wales, Australia). *Pathology* 9(4):353-358; 1977.

An unusual case of gastric carcinoid tumor producing multiple biogenic amines is described in a patient with pernicious anemia. The patient was a 59-yr-old man who presented with a 3-month history of anorexia, abdominal discomfort, and clinical symptoms and signs of pernicious anemia. Anorexia and abdominal discomfort persisted after the patient was started on therapy for anemia, and epigastric tenderness was present. Gastroscopy revealed atrophic gastritis and a polypoid lesion, which was situated at the level of the mid-body on the greater curvature. The lesion had histological features of a carcinoid tumor or a related form of polypeptide "APUDoma." The serum glucagon levels were normal, but serum gastrin was greatly increased (2,650 ± 300 pM). Histopathological examination of the tumor, resected at laparotomy, showed uniform cells arranged partly in a trabecular pattern and partly forming solid masses. Ultrastructural examination showed that the neoplastic cells were tightly packed and irregularly polyhedral with well-defined cell and nuclear membranes. Two forms of secretory granules were identified, one being intensely electron dense and homogeneous and the other less dense with a vague and irregularly electron-lucent internal structure. Both forms of granules were bound by irregular limiting membranes, and the electron-dense variety was the most prevalent. The tumor contained the following biogenic amines: norepinephrine (26.8 μg/g), epinephrine (7.9 μg/g), and 5-hydroxytryptamine (1.1 μg/g). tumor gastrin concentration was 5,000 pg/g. Carci noid tumors may be associated with a wide variety clinical syndromes and the production of biogenic amines or polypeptides or a combination of these products.

7523 THE TWO HISTOLOGICAL TYPES OF GASTRIC CARCINOMA IN NORTHERN NIGERIA.

(Eng.) Mabogunje, O. A.; Subbuswamy, S. G.; Lawrie, J. H (Ahmadu Bello Univ. Teaching Hosp., Zaria, Nigeri *Gut* 19(5):425-429; 1978.

The proportion of two histological types of gastr carcinoma (intestinal type, characterized by the formation of glandular structures and islands and the diffuse type, with cells tending to separate and infiltrate individually) was investigated in 65 specimens from Northern Nigerian patients. Fo tumors were intestinal, 16 were diffuse, 2 were mixed, and 7 were unclassifiable. The intestinal type occurred with equal frequency as the diffuse type with regard to age group and sex distributio

7524 CARCINOMA OF THE STUMP AFTER GASTRIC RE SECTION FOR GASTRIC ULCER AND ADENOMATO POLYPS.

(Ger.) Wanzjan, E. N.; Astrozhnikov, Y. V.; Tschernousov, A. F. (All Union Res. Inst. for Clinical and Experimental Surgery, B. Pirogovskaj 2/6, 119874 Moscow, USSR). *Zentralbl. Chir.* 102 (22):1358-1364; 1977.

Primary carcinoma of gastric stump was found in patients who had undergone gastric resection for ulcer or for solitary or multiple adenomatous polyps. Thirty-five patients underwent surgery gastric stump carcinoma; the surgery was radical in 21. Extirpation of the gastric stump was performed in 12 patients and subtotal or combined subtotal resection in 9. Palliative surgery was performed on four patients, and the others had e ploratory laparotomy. The postoperative mortali was 4/35. Five patients died during the first 2 after surgery, five survived 2 yr, two survived 3-5 yr, and one has been alive for 5 yr and 5 months. Extirpation is the method of choice in the treatment of primary carcinoma of the gastric stump, while subtotal resection is recommended for primary exophytic carcinoma and for old and weakened patients.

7525 THE RISK FOR GASTRIC CARCINOMA AFTER PARTIAL GASTRECTOMY.

(Eng.) Domellof, L.; Janunger, K. G. (Univ. Hosp., S-901 85 Umea, Sweden). *Am. J. Surg.* 134(5):581-584; 1977.

A statistical evaluation of the incidence of gastric stump carcinoma in patients previously operated upon for ulcer disease was undertaken to define a risk group. Systematic endoscopic follow-up of patients operated upon since 1973 revealed 10 such cases. In addition, 188 patients who had undergone Billroth I resection and 488 patients who had undergone Billroth II resection (in 1952-1966) were followed up; 41/188 and 101/488 were unavailable for or refused the study and 39/188 and 159/488 were already dead, 3/159 from stump carcinoma. Gastroscopy of the remaining 108 and 228 patients revealed stump carcinoma in 4 and 7, resp. Of the 14 cases developing stump carcinoma after resection, ulcer disease was known in 10, so that a total of 20 cases (18 men) were analyzed. The risk ratio (observed:expected [O:E] number of stomach carcinoma cases) became <1 at 9-11 yr postoperatively, so that the postoperative periods 0-8 yr, 9-11 yr, and ≥12 yr were used in the analysis, which was corrected for known factors of bias (e.g., sex, age, area of residence); it was possible to combine the 20 cases without introducing bias. The O:E ratio was 0:3.3 at 0-8 yr, 2:2.1 at 9-11 yr, and 12:4.7 at ≥12 yr, the latter ratio being significant ($p=0.007$ for men, $p=0.006$ for women); the latter ratio became 12:6.7 and was not significant if the extreme assumption was made that all stump carcinomas are diagnosed 5 yr earlier than if no follow-up was performed. When the estimated annual incidence of stomach carcinoma in operated and nonoperated men 50-85 yr old was calculated, the expected number was higher in the operated patients, with the 50-55 yr age group having an expectation 12 times greater than that of the oldest group. There was a tendency for older patients undergoing operation for gastric ulcer to have a shorter time interval between operation and the development of carcinoma, whereas age at operation for duodenal ulcer seemed not to have any influence on the interval. There was no significant difference in the O:E ratio between gastric (5:2.9) and duodenal (7:4.4) ulcer patients. It is concluded that male patients resected for benign ulcer disease more than 11 yr previously constitute a risk group.

7526 GASTRIC DIVERTICULA FOLLOWING SUBTOTAL GASTRECTOMY.

(Eng.) Mihas, A. A.; Han, S. (Div. Gastroenterology, Univ. Alabama, Birmingham, AL 35294). *Gastrointest. Radiol.* 2(3):263-265; 1977.

The cases of four patients in whom gastric diverticula developed in unusual sites following subtotal gastrectomy are presented. The first patient was a 22-yr-old woman with a life-long history of upper gastrointestinal problems. She had previously undergone a posterior gastrojejunostomy for duodenal obstruction, excision of a congenital duodenal diaphragm together with jejunojejunostomy, and a pyloroplasty with a side-to-side duodenojejunostomy for pyloric obstruction. Following the latter operation, she continued having postprandial epigastric pain and vomiting. An upper gastrointestinal series showed prolapse of gastric mucosa into a large duodenum, producing symmetrical defects of the gastroduodenal junction, and a gastric diverticulum. Endoscopy revealed hyperplastic mucosa obstructing the pyloric stoma and a greatly dilated duodenum. A large polypoid mass of gastric mucosa that appeared to be in a position to obstruct intermittently the pylorus and produce a diverticulum of the greater curvature was found at laparotomy. The mass was excised with apparently satisfactory results. The second patient was a 56-yr-old man who had undergone a subtotal gastrectomy with Billroth II anastomosis for peptic ulcer disease 5 yr before developing a gastric diverticulum proximal to the gastrojejunostomy. The third patient was a 58-yr-old man who had undergone a vagotomy and partial gastrectomy with a Billroth II anastomosis for a bleeding duodenal ulcer 17 yr prior to developing almost complete gastric obstruction. Upper gastrointestinal series showed a round mass in both afferent and efferent loops at the anastomosis. At laparotomy, the mass was found to be produced by a prolapsed gastric mucosa that was greatly redundant and hypertrophied. The fourth patient, a 44-yr-old woman, developed a gastric diverticulum simulating an ulcer on the lesser curvature. She had previously undergone subtotal gastrectomy with Billroth II anastomosis followed by further gastric resection with Roux-en-Y anastomosis and vagotomy for duodenal ulcer disease.

7527 MORPHOLOGY OF THE GASTRIC MUCOSA, GASTRIC SECRETION AND SERUM GASTRIN CONCENTRATION FOLLOWING A TEST MEAL.

(Eng.) Kaess, H.; Cheli, R.; De Benedetti, F.; Ciancamerla, D.; Dorner, M. (Stadt. Krankenhaus Munchen-Schwabing, Kolnerplatz 1, D-8000 Munich 40, W. Germany). *Digestion* 17(1): 18-28; 1978.

To investigate the gastrin response to a physiological stimulus, the relationship between the histological state of the antral and fundic mucosa, HCl secretion, and serum gastrin response after a test meal of a liquid meat extract was studied in 32 subjects with dyspepsia. In the patients with a normal fundic mucosa (11) or superficial gastritis (3), there was a significant increase in fasting serum gastrin concentration (from 74 ± 4 to 97 ± 5 pg/ml, $p<0.01$) in response to the test meal. In patients with atrophic lesions of the fundic mucosa (18), serum gastrin levels in the fasting state were significantly higher (218 ± 40 pg/ml, $p<0.025$) than in the normal group, and also significantly higher (290 ± 59 pg/ml, $p<0.025$) following the test meal. Fasting and postprandial gastrin concentrations were lower in the 14 patients with antral atrophy than in the 18 with a normal antral mucosa or superficial antral gastritis. The highest levels for basal (324 pg/ml) and postprandial gastrinemia (peak 436 ± 116 pg/ml) occurred in the group of nine patients having a normal antrum associated with atrophic lesions of the fundus. The integrated gastrin response was 4.0 ± 0.8 ng/90 min ($p<0.05$) in the group with atrophic lesions of the fundus and 0.9 ± 0.2 ng/90 min in those with a normal fundus. Patients with atrophic lesions of the antrum had a gastrin response of 1.1 ± 0.3 ng/90 min compared to 3.9 ± 1.1 ng/90 min in the normal antrum group. Basal hypergastrinemia (>100 pg/ml) was seen in 10/14 patients with poststimulating achlorhydria. Gastrin output was not affected by the test meal in patients with atrophic antral lesions, but in those with normal antrum and atrophic fundus, feeding provoked a significant ($p<0.01$) gastrin response (7.0 ± 1.9 ng/90 min) compared to subjects with normal antrum and fundus (0.9 ± 0.2 ng/90 min). The integrated gastrin output was 0-2.3 pg/90 min in subjects with HCl secretion after maximal stimulation. Elevated gastrin responses (up to 21.2 pg/90 min) were observed in subjects with poststimulatory achlorhydria. There was a significant correlation between basal gastrin concentration and integrated gastrin output in subjects presenting achlorhydria and a normal antrum ($r=0.94$) in contrast to those with achlorhydria and atrophic antral lesions. The results confirm previous investigations on serum gastrin concentration and chronic atrophic gastritis and favor a major role for HCl secretion in gastrin response.

7528 PROTEINLOSING GASTROPATHY WITH GASTRIC HYPERSECRETION OF ACID (H+) AND PEPSIN AND HYPERGASTRINEMIA. A CASE REPORT. (Eng.)

Waldum, H. L.; Burhol, P. G.; Nordoe, A.; Kearney, M. (Univ. Hosp., 9012 Tromsoe, Norway). *Acta Hepatogastroenterol.* 24(4):296-301; 1977.

The case of a patient with protein-losing gastropathy, acid and pepsin hypersecretion, and hypergastrinemia is reported. The patient, a 21-yr-old woman, presented with peripheral edema and slight anemia. An upper gastrointestinal series demonstrated gastric folds and two diverticula in the duodenum. Gastroscopy confirmed this appearance, and biopsy revealed changes of chronic superficial gastritis, with atrophy of the superficial glands and infiltration of the lamina propria with nonspecific inflammatory cells. The basal acid and pepsin outputs were 19.1 mEq/hr and 241 mg/hr, resp., and the pentagastrin-stimulated outputs were 39.7 mEq/hr and 485 mg/hr, resp. The fasting serum gastrin level was also elevated, at levels of 216 to 370 pg/ml. The diagnosis of Zollinger-Ellison syndrome was excluded, as the acid secretion and serum gastrin level decreased during the 22-month observation period. In addition, the basal gastric acid concentration (55.1 mEq/l) was lower than usually found in patients with gastrinoma. Acid secretion fell after both secretin and glucagon injection (1.9 and 1.1 mEq/hr, resp.), making the diagnosis of Zollinger-Ellison syndrome even more unlikely. The pepsin output in this patient was even more increased than the acid output, which is contrary to the usual findings in gastrinoma. The giant gastric folds were less prominent at repeat gastroscopy at the end of the observation period.

7529 PRIMARY GASTRIC LYMPHOID PROLIFERATIONS: IMMUNOLOGICAL CRITERIA TO DISTINGUISH GASTRIC LYMPHOMA FROM REACTIVE HYPERPLASIA. (Eng.)

Palestro, G.; Poggio, E.; Leonardo, E.; Coda, R. (Istituto di Anatomia e Istologia Patologica, Universita di Torino, Via Santena 7, 10126, Torino, Italy). *Oncology* 34(4):164-167; 1977.

Six patients with a marked gastric lymphoid "hyperplasia," two of these with generalized lymphoma and the others suspected for primary gastric lymphoma, were investigated to discriminate between simple reactive hyperplasias and lymphomatous proliferations. The histological and ultrastructural data confirmed the difficulty of distinguishing reactive lymphoid hyperplasia from malignant lymphoma. In all cases, the presence of inflammatory cells other than mature lymphocytes and of true lymphoid germinal centers did not give an absolutely useful diagnostic criterion. These features, less or more evident, were associated with large and coarsely shaped and irregularly distributed nodules, many of which lacked a recognizable germinal center; moreover, numerous mitoses were noted in the extranodular areas. On histological and clinical grounds, four cases with conspicuous lymphoid hyperplasia and infiltration of the gastric wall were interpreted as primary gastric lymphomas; in the other two, an associated generalized lymphoma was present. In the two patients with generalized lymphoma and gastric involvement and in two of the four with primary striking gastric lymphoid hyperplasia, the number of B lymphocytes was increased in both peripheral blood and in the lymph node suspensions, whereas those in the remaining two patients were within the normal range. On the other hand, E-rosetting and T-cells had lower than normal levels in the same four patients. In the peripheral blood, the percentages of E-rosetting cells and T lymphocytes were 25% and 30%, 40% and 20%, 34% and 30%, an 35% and 25%, resp., in the four patients, whereas th corresponding values in the other two patients were 58% and 65% and 54% and 60%, which were within the normal range. Lymphocyte suspensions from perigastr lymph nodes of one patient with generalized lymphoma and three patients with primary gastric lymphoid hyperplasia were tested. An increased number of B lymp ocytes was found in the patient with generalized lymphoma, whereas only the one patient with hyperplasia and increased B lymphocytes in the blood had an increased number of B lymphocytes in the lymphocyte suspension. These data suggest that the primitive exuberant gastric lymphoid hyperplasias may be distinguished in two sets as follows: the first withou immunological disorders and the second with peripheral blood signs of immunological alterations.

7530 GASTRIC POLYPOSIS DUE TO MULTIPLE HYPERPLASTIC ADENOMATOUS POLYPS. (Eng.)

Weaver, G. A.; Kleinman, M. S. (Dept. Medicine, Mary Imogene Bassett Hosp., Cooperstown, NY 13326). *Am. J. Dig. Dis.* 23(4):346-352; 1978.

Four cases of gastric polyposis (multiple gastric polyps numbering more than 5 in one case and more than 10 in the others) are presented in which the polyps involved diffusely a specific region of the stomach. Presenting symptoms included a lump in the stomach, nausea for approximately 6 months, intermittent upper abdominal pain for 5 yr, and abdominal pain developing after an episode of diarrhea. Results of upper gastrointestinal series showed polypoid antral lesions in cases 1 and 2 and multiple filling defects in case 4; results were normal in case 3. Gastric analysis results were equivocal for gastric acid in case 1, showed no aci the fasting state or with betazole stimulation in es 2 and 4, and showed 2 mEq of acid in a 1-hr al collection and 27 mEq in a 1-hr betazole stimted collection in case 3. In cases 1, 2, and 3, oscopy or gastroscopy revealed multiple polypoid ions in the antrum. In case 4, most lesions e present on the greater curvature and were ated at the junction of the antrum and the y. In all cases, superficial biopsies of polyps revealed ulcerated gastric mucosa infiltration of gastric mucosa with inflamory cells. In cases 2 and 4, several biopsies ealed tissue granulation, and in case 4, re was some cystic dilatation of the gastric nds. These hyperplastic adenomatous polyps quently appeared as ulcerated elevations of oscopically normal-appearing gastric mucosa. polyps ranged in appearance from type I to e III as classified by Yamada. Patients 2, nd 4 were taking thiazide diuretics; pats 2 and 4 were taking other drugs as well; ients 2, 3, and 4 were taking thiazide diuretics; ients 2 and 4 were taking other drugs as well; patients 2 and 3 consumed alcohol. Patient 4 pernicious anemia and marked bile reflux. The es of these factors in the pathogenesis of gas- polyposis require further consideration. authors conclude that, since carcinoma occurring these polyps is rare, nonoperative management is ably indicated.

SPONTANEOUS DISAPPEARANCE OF GASTRIC POLYPS: REPORT OF FOUR CASES.

(Eng.) amoto, Y.; Nishitani, H.; Oshiumi, Y.; Okawa, (Faculty Medicine, Kyushu Univ., Fukuoka, an). *Am. J. Roentgenol.* 129(5):893-897; 1977.

cases of 4 patients among 88 in whom benign ric polyps were found are presented to illuse the rare outcome in which these polyps taneously disappeared or regressed. A smooth nculated polyp 0.8 cm in diameter that became bulated over 22 months and a 3.0 x 1.5-cm polyp formed during these 22 months in a 55-yr-old n were followed up at 24 months to reveal that large polyp had broken off at its base, leaving a small hemispherical stump. A pedunculated x 1.1-cm polyp in a 36-yr-old woman was foled up at 4.5 yr to reveal only a small hemierical stump 1-cm in diameter, indicating that polyp had broken off at its base. A pedunted 3.5 x 1.5-cm polyp was found in a 62-yr- woman; 2 months later, the polyp surface was ed, hemorrhagic, and irregular; 23 months r, the polyp had decreased in size to 1.5 x cm. A hemispherical polyp 0.8 cm in diameter found in a 51-yr-old woman; it was unchanged onths later; but 4 yr later, the polyp could be detected, and the gastric mucosa was normal he polyp's former site.

2 THE EFFECT OF ANTRECTOMY OR TOTAL GASTRECTOMY ON CALCIUM-INDUCED GASTRIC SE- ION AND GASTRIN RELEASE IN MAN.

(Ger.) Schafmayer, A.; Borger, H. W.; Stuhler, T.; Siewert, R.; Becker, H. D. (Klinik und Poliklinik fur Allgemeinchirurgie, Universitat Gottingen, Gosslerstrasse 10, D-3400 Gottingen, W. Germany). *Klin. Wochenschr.* 55(23):1159-1163; 1977.

The effect of antrectomy or of total gastrectomy on calcium-induced gastric secretion and gastrin release was studied by radioimmunoassay in 8 patients who underwent antrectomy and gastroduodenostomy (Billroth I), 12 patients who underwent antrectomy and gastrojejunostomy (Billroth II), 9 patients who underwent total gastrectomy and esophagojejunostomy, and 20 healthy subjects not operated on. The probands received calcium infusion (4 mg/kg/hr for 4.5 hr, i.v.) as calcium gluconate accompanied by a slow i.v. infusion of 4 mg/kg [illegible] during the first 30 min. The basal serum gastrin level, peak gastrin level, and total gastrin release were reduced in the patients compared with the controls. In the control, calcium stimulated gastric secretion and gastrin release. After antrectomy, gastric secretion was still stimulated by calcium without any change in the serum gastrin levels. After total gastrectomy, the basal serum gastrin concentration was further reduced; calcium did not cause gastrin release. The results show that calcium-induced gastric secretion is due to direct action on the parietal cells and to gastrin release from the antrum.

7533 GASTRIC VARICES: PROBLEM IN DIAGNOSIS.

(Eng.) Marshall, J. P., II; Smith, P. D.; Hoyumpa, A. M., Jr. (Veterans Admin. Hosp., Nashville, TN 37203). *Am. J. Dig. Dis.* 22(11): 947-955; 1977.

Three cases that illustrate the characteristics of gastric varices and factors in their diagnosis and management are presented. The first patient was a 39-yr-old alcoholic man with recurrent pancreatitis, abdominal pain, and gastric bleeding. Endoscopy repeatedly demonstrated large gastric "folds" corresponding to a mass seen in a barium study. The findings in both studies were misinterpreted; the correct preoperative diagnosis of splenic vein obstruction and secondary gastric varices was finally established by arteriography and splenoportography. In the second patient, a 75-yr-old alcoholic man with recurrent vomiting, barium studies revealed a mass in the fundus that was thought to be a neoplasm. The correct diagnosis was made on endoscopy and confirmed by arteriography. The third patient was a 42-yr-old alcoholic with a long history of chronic pancreatitis. He presented with a 1-week history of severe abdominal pain. Both radiologic and endoscopic examination suggested a malignancy, and a biopsy was taken during endoscopy. Only normal gastric mucosa was seen, and no bleeding ensued. A celiac angiogram demonstrated almost total occlusion of the splenic vein in the region of the midpancreas with marked collateral filling of the short gastric veins and gastroepiploic veins. The patient's symptoms resolved on conservative management with nasogastric suction, possibly due to relief of splenic vein obstruction or development of collateral circulation. These cases show the value of arteriography in the diagnosis of gastric varices.

Peptic Ulcers

7 THE GIANT DUODENAL ULCER SYNDROME. (Eng.)

Segal, I.; Solomon, A.; Ou Tim, L.; Law-
, H. H.; Sottomayor, M. C. C. G. (Baragwanath
., Johannesburg, South Africa). *S. Afr. Med.*
52(18):724-727; 1977.

cases of 13 patients with giant duodenal ulcer
J) are reviewed with respect to clinical, rad-
gical, endoscopic, and pathological features,
the differential diagnosis and treatment of
s entity are briefly discussed. The symptoms
e characterized by a chronic history of exacer-
ions and remissions. Pain was often situated
he right hypochondrium, always radiated to the
, and was aggravated by food and antacids.
ting, weight loss (all cases), hematemesis or
na due to gastrointestinal tract bleeding
cases), pallor, and mild upper abdominal
erness (especially in the epigastrium) were also
rved. The ulcer may be so large that the crater
mimic a normal duodenal bulb in radiological ex-
ations; other radiological signs may include a
lous or destroyed pylorus, a crater of con-
t size and shape without contractions, an
nt mucosal pattern over the crater and con-
ction distal to the crater, single or multiple
ing defects in the base of the ulcer, compres-
of the third portion of the duodenum by the
ntery due to the inflammatory process, a per-
ent and unchanging round collection of air in
crater, and retention of contrast material
he ulcer for several hours after examination.
scopy reveals a widened, edematous, hyperemic
ric sphincter; the ulcer is clearly seen as a
necrotic trough extending circumferentially
nd the whole mucosa, virtually replacing the
enal wall. Pathologically, the crater often
aces the duodenal bulb and erodes into the
of the pancreas, forming a walled-off perfor-
n; distortion of the gastric antrum by the
ammatory process extends into the mesenteric
causing compression of the third portion of
duodenum; and adherence to surrounding structure
ommon. Histology confirms the benign nature
he lesion. The history and presentation of
are confusing and protean, complicating the
nosis. Radiology differentiates GDU clearly
posterior penetrating ulcer. Treatment is
important because the incidence of serious
lications and the mortality rate (40-67% in
iously reported series) are quite high. Of
13 patients in this series, 1 died, 9 under-
surgery, and 3 were treated medically (of
1 improved and 2 later required surgery).

SERUM GASTRIC INHIBITORY POLYPEPTIDE (GIP) IN DUODENAL ULCER DISEASE: RELATIONSHIP
UCOSE TOLERANCE, INSULIN, AND GASTRIN RELEASE.

.) Arnold, R.; Creutzfeldt, W.; Ebert, R.;
er, H. D.; Borger, H. W.; Schafmayer, A. (Medi-
sche Univ.-Klinik, Humboldtallee 1, D-3400
Gottingen, W. Germany). *Scand. J. Gastroenterol.*
13(1):41-47; 1978.

Basal and food-stimulated serum immunoreactive gastric inhibitory polypeptide (IR-GIP), gastrin (IRG), and insulin (IRI) levels were estimated in 41 normal weight patients with chronic duodenal ulcer disease and 25 weight- and age-matched controls to determine whether gastric acid hypersecretion in duodenal ulcer disease is related to a faulty GIP secretion. A pathological glucose tolerance (a 60- plus 120-min sum of blood glucose levels >310 mg/dl) was observed in 15/41 patients during standard oral glucose tolerance tests with 75 g of glucose and in 28/41 patients after ingestion of a high-calorie test meal (1,031 calories ingested within 10 min). The test meal induced a rapid rise of IR-GIP, IRI, glucose, and IRG in duodenal ulcer patients and controls for 5 hr, but all four parameters increased to significantly higher ($p<0.02$) levels in the patients; serum IR-GIP increased most markedly in patients with a pathological glucose tolerance response during the test meal and remained significantly elevated for 5 hr. The GIP response of patients with a normal glucose tolerance response to the test meal was less marked and only higher than the controls for 2 hr. The duodenal ulcer patients had significantly greater integrated IR-GIP, IRI, and glucose responses than did the controls (IR-GIP: 266.4 ± 27.3 and 108.1 ± 10.9 ng/ml/180 min, resp.; IRI: 10.4 ± 1.3 and 4.9 ± 0.6 mU/ml/180 min, resp.; glucose: 13.9 ± 1.3 and 4.7 ± 0.7 g/100 ml/180 min, resp., $p<0.02$ in all cases). These responses were significantly greater in patients with pathological than in those with normal glucose responses (IR-GIP: 302.8 ± 18.4 and 196.2 ± 12.8 ng/ml/180 min, resp., $p<0.005$; IRI: 13.4 ± 0.6 and 7.2 ± 0.3 mU/ml/180 min, resp., $p<0.02$; glucose: 18.5 ± 0.5 and 8.7 ± 0.3 g/100 ml/180 min, resp., $p<0.02$). The results rule out the possibility that hyposecretion of GIP is a factor in the pathogenesis of gastric acid hypersecretion in duodenal ulcer patients.

7589 GASTRIC MUCOSAL HISTAMINE IN DUODENAL-ULCER PATIENTS: RELEASE BY SECRETIN.

(Eng.) Domschke, W.; Subramanian, N.; Mitznegg, P.; Baenkler, H. W.; Domschke, S.; Wunsch, E. (Dept. Medicine, Univ. Erlangen-Nurnberg, Krankenhausstr. 12, D-8520 Erlangen, W. Germany). *Acta Hepato-gastroenterol. (Stuttg.)* 24(6):444-446; 1977.

Since many duodenal ulcer patients manifest a local anaphylactic skin reaction to intradermal secretin, studies were carried out to determine whether secretin-induced histamine release also occurs in the gastrointestinal tract of duodenal ulcer patients. Biopsy samples from the fundus of five duodenal ulcer patients with an anaphylactic skin reaction to intradermal secretin and of four healthy controls were superfused with phosphate buffer alone or with buffer containing synthetic secretin

(20 Clinical U/ml). Mucosal specimens from the duodenal ulcer patients released histamine in response to secretin, reaching a 65% increase above the basal level ($p<0.05$), whereas specimens from the controls showed no change in response to the infusion. The histamine content of untreated gastric mucosa was about twice as high as that in controls ($p<0.02$). The elevated mucosal histamine could account for the basal and stimulated gastric hypersecretion seen in duodenal ulcer patients. Additionally, the results are compatible with the concept that, in a certain type of duodenal ulceration, secretin stimulates rather than inhibits gastric secretion.

7590 THE EFFECT OF ORAL LOCAL ANAESTHETIC AND ALKALI ON BASAL AND FOOD-STIMULATED SERUM GASTRIN LEVELS IN PATIENTS WITH DUODENAL ULCER.

(Eng.) Barbezat, G. O.; Vinik, A. I.; Grant, B. (Groote Schuur Hosp., Observatory, 7925, Cape, South Africa). *Scand. J. Gastroenterol.* 13(3):321-323; 1978.

The effect of p.o. therapeutic doses of alkali (aluminum hydroxide, 1.2 g plus magnesium hydroxide, 0.4 g), local anesthetic (oxethazaine, 40 mg), a combination of alkali and anesthetic, or water (20 ml) as control on basal and food-stimulated serum gastrin levels was investigated in 12 asymptomatic patients with duodenal ulcer. The basal serum gastrin levels were all within normal limits. Treatment with any of the three agents did not significantly alter these concentrations. The ingestion of meat extract was associated with a mean rise in serum gastrin levels in all treatment groups. Fifteen minutes after the meal, patients pretreated with oxethazaine had significantly lower serum gastrin levels than did those who received water ($p<0.05$), alkali and oxethazaine ($p<0.01$), or alkali alone ($p<0.001$). There was no significant difference among the water, alkali plus oxethazaine, or alkali treated groups. After a further 15 min, only the alkali and the oxethazaine groups showed any significant difference from controls ($p<0.05$). This study confirms that noncalcium-containing alkalis, whether given alone or with a local anesthetic, do not alter basal serum gastrin levels in man.

7591 DOUBLE-BLIND CONTROLLED TRIAL OF AMYLOPECTIN SULPHATE (DEPEPSEN) IN THE SYMPTOMATIC TREATMENT OF DUODENAL ULCER.

(Eng.) Baron, J. H.; Gribble, R. J. N.; Holdstock, D. J.; Misiewicz, J. J. (Hammersmith Hosp., London W12 OHS, England). *Gut* 18(9):723-724; 1977.

A double-blind controlled trial of amylopectin sulfate (Depepsen) in the treatment of duodenal ulcer was carried out in male patients with radiological evidence of duodenal ulcer crater or deformity in the previous 2 yr, a 6-month to 5-yr history of duodenal ulcer symptoms, and ulcer pain on at least 3 of 7 days prior to admission to the trial. The patients received their customary antacids and either amylopectin sulfate (500 mg, tablet, 20 patients) or identically appearing placebo (500 mg dextrose, 21 patients) to be chewed and swallowed with a drink every 2 hr for six dose day. The patients kept diary cards recording the presence, absence, and severity (0, 1, or 2) of pain and the number of test and antacid tablets co sumed each day, which were collected every 2 weeks for 6 weeks. Duodenoscopy was not available when the study was undertaken. Diary cards were satisfactorily completed by 12/20 and 16/21 patients in the two groups, resp. Depepsen had no advantage over placebo with respect to mean number of days and nights with ulcer pain/patient, mean number of antacid tablets consumed/patient/week, or the severity of pain.

7592 VARIATIONS IN SERUM PROLACTIN FOLLOWING CIMETIDINE TREATMENT FOR PEPTIC ULCER DISEASE.

(Eng.) Delle Fave, G. F.; Tamburrano, G.; De Magistris, L.; Natoli, C.; Santoro, M. L.; Carratu, R.; *et al.* (Cattedra di Gastroenterologia II Clinica Medica, Policlinico Umberto I, 00100 Roma, Italy). *Rend. Gastroenterol.* 9(2):142-143; 1977.

Variations in serum prolactin levels were studied in 10 patients before and after cimetidine treatment for peptic ulcer disease. The first group of patients (5 men and 2 women, aged 27-60 yr) received 1.6 g of cimetidine daily, p.o., for duodenal ulcer (2 cases), recurrent postgastrectomy ulcer (3 cases), or Zollinger-Ellison syndrome. The second group (3 men, aged 35-65 yr) received 1.0 g of cimetidine daily for duodenal ulcer. The drug was given in four daily doses for 8 weeks. The pretreatment prolactin levels were within normal limits in all patients. In the patients who received the higher dose of cimetidine, these values showed a constant increase over the 8-week treatment period, reaching 12.5-32 ng/ml (mean, 2 2.9, $p<0.001$). These values returned to normal 3 to 4 weeks after the treatment was discontinued. There was no significant change in the prolactin levels in patients who received the lower dose of cimetidine. Gynecomastia and galactorrhea were observed respectively in two of the seven patient who received the higher dose and in none of the patients who received the lower dose. These observations show that the effect of cimetidine on prolactin levels is probably dose-dependent. The mechanism responsible remains to be elucidated.

7593 THE USE OF GLIPTIDE IN PATIENTS WITH DUODENAL ULCERS.

(Eng.) Gilmore, A. M.; McCarthy, C. F.; Feighery, C.; Weir, D. G.; O'Neill, M.; Whelton, M.; *et al.* (Regional Hosp., Galway, Ireland). *Ir. Med. J.* 70(20):615-617; 19

A double-blind study of the value of Gliptide (a sulfaglycopeptide, 50 mg [2 tablets] t.i.d.) in t treatment of duodenal ulcers was carried out in 7 patients, 39 of whom received this drug and 37 of whom received placebo. Significantly more ulcers healed in the Gliptide group than in the placebo group ($p<0.02$) during the 8 weeks of observation. Gliptide treatment was also significantly better

lacebo in the treatment of ulcers in patients in whom
ome deformity of the duodenal cap was present (p<
.01). Although this treatment was superior to
lacebo, only 50% of ulcers had healed at 8 weeks.

594 METHYL-PROSTAGLANDIN E_2 ANALOGUES FOR HEALING OF GASTRODUODENAL ULCERS. (Eng.)
ybicka, J.; Gibinski, K. (Silesian Sch. Medicine,
atowice, Poland). *Scand. J. Gastroenterol.* 13(2):
55-159; 1978.

double-blind clinical trial of the value of meth-
l-prostaglandin E_2 ($mPGE_2$) analogues in the treat-
ent of ulcers was carried out in 117 men with gas-
roduodenal ulcers. Thirty-six patients received
lacebo, 25 received 15(R) 15-$mPGE_2$ methyl ester
$mPGE_2$ R, 2.0 μg/kg, t.i.d.), 36 received 15(S)
5-$mPGE_2$ methyl ester ($mPGE_2$ S, 1.5 μg/kg, 3-4
imes/day), and 20 received 16,16-dimethyl PGE_2
di $mPGE_2$, 1.5 μg/kg, 3-4 times/day). Prostaglandin
reatment resulted in significant decreases in both
asal acid output ($p<0.05$, $p<0.001$, $p<0.001$, and
<0.001 for $mPGE_2$ R, $mPGE_2$ S, di $mPGE_2$, and pooled
nalogues, resp.) and mean acid output ($p<0.01$,
<0.001, $p<0.001$, and $p<0.001$, resp.) in comparison
ith the levels in controls. The number of duodenal
cers that cicatricized was significantly higher
<0.01) in the PGE_2-treated patients than that in
ntrols, and this was especially true in patients
eated with $mPGE_2$ S ($p<0.001$, in comparison with
ntrols). This healing was not seen in gastric
cers.

95 TREATMENT OF PEPTIC ULCER IN ZOLLINGER-ELLISON SYNDROME WITH HISTAMINE H_2 RE-
PTOR ANTAGONISTS. (Ger.) Hausamen, T. U.;
itsch, W. P.; Scholten, T.; Jungblut, R.; Stroh-
yer, G. (Stadtische Kliniken, Beurhausstr. 40,
00 Dortmund, W. Germany). *Dtsch. Med. Wochenschr.*
2(47):1709-1712; 1977.

ur patients with recurrent peptic ulcer due to
llinger-Ellison syndrome were treated with the
stamine H_2-receptor antagonists cimetidine and
tiamide. All patients were treated with cimeti-
ne (5 x 200 mg/day) for 1.5-4.5 months. One
tient was at first treated with metiamide in the
me dosage, and another received methantheline
omide (50 mg) in addition to metiamide. The
cerations were completely healed in all patients.
o patients developed recurrent ulcers after the
eatment was stopped, but responded to a second
urse. One patient developed acute hepatitis B
llowing the cimetidine treatment; the course of
e hepatitis may have been unfavorably affected
cimetidine. No other side-effects were noted,
r was there any significant change in the basal
rum gastrin concentration or an increase in the
secretion. While total gastrectomy remains
e treatment of choice in Zollinger-Ellison syn-
ome, cimetidine treatment should be considered
the patient refuses operation or if surgery is
feasible in view of the poor general condition
the patient.

21 ENTEROKINASE ACTIVITY IN HUMAN INTESTINALIZED GASTRIC MUCOSA.

(Eng.) Simon,
; Figus, A. I. (Hospital Jaszbereny, H-5101 Jasz-
reny, Hungary). *Digestion* 16(1/2):48-50; 1977.

terokinase activity was examined in six homogen-
ed specimens of human gastric tissue with in-
stinal metaplasia, three specimens of normal
stric mucosa, and three specimens of normal du-
enal mucosa. Enterokinase activity was demonstra-
d in normal duodenal mucosa at a level of 34.3 ±
2 U/g mucosa, while no activity was found in the
rmal gastric mucosa. Enterokinase activity was
monstrated in the homogenate of intestinalized gas-
c mucosa (5.41 ± 2.11 U/g), and the level was in-
eased in homogenates of biopsy specimens taken 10
after the subjects had received an i.v. injection
1 mg of glucagon (8.28 ± 3.75 U/g, $p<0.01$). These
ervations support the hypothesis that intes-
alized brush border cells of gastric mucosa may
e the original absorptive and secretory capacity
true intestinal epithelium.

2 ABNORMAL DUODENAL LOOP AND PYLORIC REGURGITATION.

(Eng.) Thommesen, P. (Muni-
al Hosp., Aarhus, Denmark). *Acta Radiol.*
agn.] *(Stock.)* 18(4):473-479; 1977.

dies were carried out in 48 patients with
er abdominal dyspepsia to investigate whether
denal anomalies and posture have any influence
pyloric regurgitation and whether a parasym-
etic drug (metochlopramide) has any effect
the regurgitation. Eleven patients had a
nal duodenal loop, 14 had a proximal duodenal
maly and passage hindrance high in the duo-
um, and 23 had a distal anomaly or a short
denal loop or combined anomaly. A tube was
sed into the descending part of the duodenum,
20 ml of contrast medium was instilled.
roscopy and exposure of the films were carried
immediately and after 4 min. Pyloric regur-
ation occurred significantly more often in the
patients with a distal anomaly, short duodenal
p, or combined anomaly (19/23; $\chi^2=12.4$, 3.84 at
evel) than in the first group (2/11). No
lent difference was demonstrated between the
t and second groups; 5 of the 14 patients in
second group had regurgitation ($\chi^2=1.20$, 3.84
% level). Regurgitation occurred in 11 of 17
ents in an erect position but in none of these
ents when they were supine. Regurgitation in
erect position was more effectively prevented
etochlopramide (20 mg, i.v.) than by placebo
2 and 2/12, resp.; $\chi^2=4.61$, 3.84 at 5% level).
results suggest that a relation exists be-
n pyloric regurgitation, the shape of the
enal loop, and the position of the patient,
that metochlopramide has an effect on the
rgitation. Distal and combined anomalies and
ort duodenal loop predispose the patient to
ric regurgitation.

JEJUNAL DIVERTICULITIS.

(Eng.) Giustra, P. E.; Killoran, P. J.; Root, J. A.; Ward, W. W. (Penobscot Bay Medical Center, Rockland, ME 04841). *Radiology* 125(3):609-611; 1977.

The cases of two patients with jejunal diverticulitis are presented. Both patients exhibited episodes of partial small bowel obstruction, acute abdominal symptoms, abdominal masses, intermittent hypochromic anemia, and recurrent diverticulitis over several years. The first patient was a 50-yr-old man in whom jejunal diverticulitis was suggested on the basis of low-grade jejunal obstruction. He responded to medical treatment, but 4.5 yr later he developed signs of generalized peritoneal irritation. Abdominal radiographs showed dilated, fluid-filled loops of small intestine thought to be consistent with adynamic ileus caused by peritonitis. The clinical diagnosis was sigmoid diverticulitis, and the patient responded to antibiotic therapy and i.v. fluids. A subsequent barium enema study was negative for sigmoid diverticulitis, and a small bowel series demonstrated extravasation of barium from a ruptured jejunal diverticulum into a sealed-off mesenteric abscess. The other patient was a 79-yr-old woman with left upper quadrant abdominal pain and a firm, nontender, movable anterior left subcostal abdominal mass. A barium enema study showed a persistent localized contour abnormality of the inferior aspect of the distal transverse colon. An upper gastrointestinal series demonstrated jejunal diverticula, but they were not readily associated with the abnormal barium study. At surgery, a 1.5-cm jejunal diverticulum was found together with an inflammatory mass. The mass adhered to the colon, although the latter was not directly involved with the abscess. The mass and two adjacent jejunal loops were resected. There were also other small adjacent jejunal diverticula. Six years later, multiple diverticula of the jejunum with secondary diverticulitis and abscess formation were found at surgery. A 4-cm pus-filled abscess space forming an adhesive S-shaped mass binding segments of the jejunum together was demonstrated. In the event of future nonspecific acute or chronic abdominal findings, previous knowledge of jejunal diverticula might suggest a diagnosis of jejunal diverticulitis and lead to barium studies sooner than would otherwise be the case.

7624 INTRAMURAL HEMORRHAGE OF THE SMALL INTESTINE.

(Eng.) Eiland, M.; Han, S. Y.; Hicks, G. M., Jr. (Radiology Associates, 1717 11th Ave., S., Birmingham, AL 35205). *JAMA* 239(2):139-142; 1978.

The roentgenographic features, course, and treatment of intramural hemorrhage are discussed, and seven illustrative cases are presented. The patients included two on anticoagulation therapy and four hemophiliacs. The hemorrhage produced one of two sets of manifestations: those related to a localized intramural mass and those related to diffuse infiltration of the bowel wall. Preliminary films of the abdomen in patients with hematoma showed a mass density with displacement of adjacent bowel. Adynamic ileus was frequently seen, and in the affected areas that contained gas, narrowing of the lumen and scalloping or thumbprinting were seen. Barium studies usually showed segmental changes, and the affected bowel was rigid. The bowel loops were separated, and the lumen was narrow but not obstructed. There was uniform thickening of the folds, which were sharply demarcated. Their parallel arrangement gave a spike-like ("coil spring") appearance. This was most frequently seen in the jejunum, where valvulae were rarely effaced. Thumbprinting was frequently well demonstrated with barium studies. Transient intussusception was present in two patients. In two patients with no discrete intramural mass, thumbprinting and the coil spring appearance were present. All but one of the patients had resolution of signs and symptoms with conservative therapy.

7625 EOSINOPHILIC GASTROENTERITIS PRESENTING AS ILEOCOLITIS.

(Eng.) Haberkern, C. M.; Christie, D. L.; Haas, J. E. (Children's Orthopedic Hosp. and Medical Center, Seattle, WA 98101). *Gastroenterology* 74(5, Part 1):896-899; 1978.

The case of a patient with clinical and roentgenographic ileocolitis diagnosed as Crohn's disease who was subsequently found to have eosinophilic gastroenteritis with colonic involvement is presented. The patient was a 15-yr-old girl with nausea, vomiting, abdominal pain, diarrhea, and weight loss. The peripheral eosinophil count was 600/mm^3. Barium enema showed marked mucosal edema and thickening of the terminal ileum, cecum, and ascending and proximal transverse colon. The upper gastrointestinal series with small bowel follow-through revealed a normal stomach and bowel to the terminal ileum, which itself appeared abnormal with fixation and mucosal thickening. Colonoscopy showed an erythematous cecum, and biopsy showed a normal colonic epithelium. The patient responded to prednisone therapy, which was given for a presumptive diagnosis of Crohn's ileocolitis, but diarrhea persisted. Prednisone therapy was tapered 1 month after hospitalization, at which time a repeat upper gastrointestinal series showed a normal terminal ileum. After discontinuing therapy, the patient again developed abdominal complaints together with urinary tract symptoms. The peripheral eosinophil count was 400/mm^3. The upper gastrointestinal series showed prominent gastric antral folds along with bowel wall thickening from the duodenum through the ileum. At laparotomy, the ascitic fluid was found to be rich in eosinophils, and multiple full thickness biopsies revealed the following: diffuse eosinophilic infiltration of the muscularis and serosa of the stomach, duodenum, jejunum, ileum, and right colon; eosinophilic infiltration of the fibrous stroma separating bladder-wall muscle bundles; and eosinophilic infiltration of a mesenteric lymph node. The patient's symptoms responded to prednisone, hydralazine, nitrofurantoin, and antacid therapy for eosinophilic gastroenterocolitis, cystitis, and a duodenal ulcer.

7626 ACUTE FULMINATING TRANSMURAL ILEOCOLITIS AFTER SMALL BOWEL BYPASS FOR MORBID OBESITY.

(Eng.) Francis, W. W.; Iannuccilli, E. (110 Lockwood St., Providence, RI 02903). *Am. J. Surg.* 135(4):524-528; 1978.

Thirty-one patients who underwent small intestinal bypass for morbid obesity were followed up. Each patient underwent an end-to-end jejuno-ileostomy anastomosing 14 inches of proximal jejunum to 4 inches of terminal ileum. Complications included hepatic insufficiency (3 patients), urinary calcul (4), inadequate weight loss (6), metabolic acidosi (3), and severe diarrhea (5). The most unusual complication occurred in a 39-yr-old woman, whose case report is presented. She developed profuse diarrhea, abdominal cramps, fever, and a weight loss of 12 pounds in 1 week at 22 months postbypass. Before this time, she had apparently responded well to the operation, losing 132 pounds during the 22-month period. Microscopic examination of a resected segment of previously bypassed and diseased small bowel revealed findings consistent with Crohn's disease. Normal bowel continuity was re-established and the diseased small bowel was resected. The patient recovered, and weighs 195 pounds following surgery and steroid therapy.

7627 CHANGES IN PLASMA AND MUSCLE FREE AMINO ACIDS IN OBESE PATIENTS AFTER JEJUNOILEAL BYPASS.

(Eng.) Goldberger, J. H.; Cha, C. J.; Randall, H. T. (Rhode Island Hosp., Providenc RI). *Surg. Forum* 28:432-435; 1977.

The nutritional state of six obese patients who underwent jejunoileal bypass was assessed by analyzing changes in plasma and muscle cell free am acids. The preoperative plasma amino acid profiles were normal in all patients. Three months postoperatively, all essential amino acids, excep methionine, and most of the nonessential amino acids in the plasma were decreased. The decrease were statistically significant in the case of va ine ($p<0.05$), lysine ($p<0.05$), and cystine (p<0.0 Only glycine (22.7%) and, occasionally, serine i creased. Intracellular free leucine, valine, and isoleucine significantly decreased postoperativel (by 49.4%, 41.2%, and 32.8%, resp., $p<0.05$). Anserine also decreased (by 34.0%), with a suggest significance ($p<0.1$). The concentrations of serine, glycine, ornithine, histidine, methionine, taurine, threonine, and proline increased postoperatively (by 57.0%, 37.8%, 33.9%, 31.4%, 10.4 24.3%, 21.0%, and 14.7%, resp.), but statistical significance could not be demonstrated in this small series. These data suggest that there are significant differences in the change in concentrations of free amino acids between plasma and muscle in obese patients who have undergone a bypass procedure, and that changes in plasma amino acid composition is not necessarily relevant to muscle and probably not to the total amino acid pool.

7628 TRAUMATIC RETROPERITONEAL RUPTURE OF TH DUODENUM.

(Eng.) Vellar, D. J.; Vella I. D. A.; Pianta, R. M. (Essex County Hosp., Eng land). *Aust. N.Z. J. Surg.* 46(3):206-208; 1976.

cases of six patients with traumatic retro-
toneal duodenal rupture are presented. The
ry was associated with a car accident in three
es, with being struck by an automobile in one
, and with being struck in the abdomen in two
s. Abdominal examination revealed tenderness,
ding, and rigidity, and these signs were max-
in the lower abdomen rather than in the upper
men in three patients. Only one patient had
abnormality in the plain x-ray film of the
men; in this case, the right psoas shadow was
terated, which suggested the possibility of
enal rupture. Four patients showed sufficient
rmalities on repeated abdominal examination
ead to laparotomy within 12 hr of injury.
e was a 66-hr delay in surgery in one patient
use of severe skeletal injuries. This patient,
the four in whom surgery was carried out within
r, survived with surgical treatment. The re-
ing patient showed indefinite signs on abdom-
palpation, but 20 hr after the injury, florid
ralized peritonitis had set in, with accompany-
generalized rigidity, guarding, and tenderness.
peration, an i.v. pyelogram showed obvious gas
he retroperitoneal tissues. After the operation,
patient became hypotensive and anuric. He had
hemolysis, and many encapsulated *Clostridium*
ringens were discovered in the peritoneal fluid.
ied 20 hr after surgery. These cases illustrate
need for early diagnosis and treatment of this
type of abdominal trauma, and emphasize that
ated abdominal examinations should be carried
t hourly or 2-hourly intervals in patients
abdominal trauma.

PREOPERATIVE ANGIOGRAPHIC DIAGNOSIS OF SMALL BOWEL LEIOMYOMAS.

(Eng.) Stothert,
, Jr.; Riaz, M. A.; Joyce, P. F.; Kaminski, D.
ept. Surgery, St. Louis Univ., St. Louis, MO).
Surg. 113(5):643-645; 1978.

reoperative angiographic diagnosis of small
leiomyomas in two patients with gastrointes-
hemorrhage, the origin of which was not evi-
by more conventional diagnostic measures, is
ibed. The first patient was an 82-yr-old man
melena. Gastroscopy and barium enema examina-
were negative, and the barium enema examina-
delayed the ability to obtain arteriographic
es. A jejunal tumor, which proved to be a
yoma, was detected by the superior mesenteric
iogram. The second patient was a 44-yr-old
ho presented with colicky lower abdominal
and developed rectal bleeding. A bleeding
ticulum was strongly suspected. Sigmoid-
ic examination showed bleeding beyond the
of the instrument. Emergency visceral angio-
revealed a tumor in the ileal branches, sug-
g leiomyoma. Both patients did well after
mors were resected. The results in these
ts and a literature review suggest that the
raphic diagnosis of leiomyoma may be indi-
by the following criteria: well-circum-
d margins of tumor stain, prominent feeding
es and veins, irregular tumor vessels giving
o a dense stain, and small areas of pooling
trast material in the mass.

7630 SARCOMA OF THE SMALL AND LARGE INTESTINES: CLINICAL FEATURES, TREATMENT AND PROGNOSIS.

(Ger.) Ruckert, K.; Gronniger, J.; Brunner, H. (Chirurgische Universitatsklinik, Langenbeckstr. 1, 6500 Mainz, W. Germany). *Dtsch. Med. Wochenschr.* 102(45):1631-1634; 1977.

The clinical aspects, therapy, and prognosis of sarcomas of the small and large intestines are described in connection with 27 cases. The sarcoma was localized to the small intestine in 20 cases, to the colon in 5, and to the rectum in 2. Reticulosarcoma was diagnosed in 10 cases, leiomyosarcoma in 4, neurogenic sarcoma in 3, round cell sarcoma in 3, lymphosarcoma in 4, pleomorphic sarcoma in 1, and rhabdomyosarcoma in 2. Reduced health status, loss of weight, pains, intestinal bleeding, changes in defecation habits, fever, colics, palpable tumor, ileus, and peritonitis were the most frequent symptoms. The tumor was locally operable and without metastases in 6 cases, locally operable with metastases in 15, and inoperable with metastases in 6. Radical segment resection was performed in 14 cases, palliative surgery in 11, and exploratory laparotomy in 2. Two patients received postoperative radiotherapy and 14 received chemotherapy (9 patients received monochemotherapy with cyclophosphamide [6 patients], adriamycin, vincristine, or mitopodoside, and 5 received polychemotherapy with vincristine, 5-fluorouracil, methotrexate, cyclophosphamide, and prednylidene). The postoperative mortality was 30%; nine patients died from sarcoma during the 1st yr. Three patients (one with reticulosarcoma, another with neurogenic sarcoma of the small intestine, and a third with lymphosarcoma of the large intestine) have been recurrence-free for 2 yr, one patient with reticulosarcoma of the small intestine has been recurrence-free for 5 yr, one with leiomyosarcoma of the small intestine has been recurrence-free for 6 yr, and one patient with round cell sarcoma of the large intestine and another with lymphosarcoma of the small intestine have been recurrence-free for 12 and 17 yr, resp.

7631 JEJUNAL ENDOCRINE TUMOUR COMPOSED OF SOMATOSTATIN AND GASTRIN CELLS AND ASSOCIATED WITH DUODENAL ULCER DISEASE.

(Eng.) Alumets, J.; Ekelund, G.; Hakanson, R.; Ljungberg, O.; Ljungqvist, U.; Sundler, F.; Tibblin, S. (Dept. Histology, Univ. Lund, Lund, Sweden). *Virchows Arch. [Pathol. Anat.]* 378(1):17-22; 1978.

The case of a patient with a malignant jejunal endocrine tumor associated with severe duodenal ulcer is presented. The tumor and a local metastasis were examined immunohistochemically. The tumor and the lymph node metastasis, located in the mesentery, were similar, composed of nests and trabecules of cells with weakly stained cytoplasm. Numerous somatostatin-immunoreactive cells were found in both the tumor and the metastasis, with less numerous cells that displayed gastrin immunoreactivity. This is the first reported case of intestinal somatostatinoma. The presence of gastrin cells in the tumor may explain the ulcer diathesis.

7632 EFFECT OF STEROIDS ON PATIENTS WITH POSTOPERATIVE BOWEL ANASTOMOTIC DYSFUNCTION. (Eng.) Toledo-Pereyra, L. H.; Guzman, I.; Yonehiro, E. G. (Henry Ford Hosp., 4011 E&R Building, 2799 W. Grand Blvd., Detroit, MI 48202). *Henry Ford Hosp. Med. J.* 25(4):285-292; 1977.

SMALL INTESTINE

Malabsorption

INCREASED TISSUE CONCENTRATIONS OF 5-HY-
DROXYTRYPTAMINE IN THE DUODENAL MUCOSA
ATIENTS WITH COELIAC DISEASE. (Eng.) Challa-
e, D. N.; Dawkins, P. D.; Baker, P. (Taunton
Somerset Hosp., Taunton, Somerset, England).
18(11):882-886; 1977.

nvestigate the relationship between the hyper-
vity or hyperplasia of enterochromaffin (EC)
s in the duodenum and the abnormalities of
droxytryptophan (5-HT) metabolism in celiac
ase, tissue levels of 5-HT were estimated in
uodenal mucosa of four adults and seven
ren with untreated celiac disease. The
ts were compared with a control group of four
s and six children with normal duodenal mu-
by light microscopy. The wet weight of duo-
tissue and its protein content were not
ficantly different in the patients and con-
. Tissue concentrations of 5-HT related
r to tissue weight or to tissue protein
significantly higher ($p<0.001$) in patients
celiac disease than in controls (10.8 ± 4.0
s 4.2 ± 2.0 μg 5-HT/g tissue or 144.5 ± 39.8
s 55.3 ± 17.9 μg 5-HT/g tissue protein).
were no significant differences between the
s and children in each group. When three
ren with celiac disease were challenged p.o.
gluten powder (10 g t.i.d. for 10 days),
tissue 5-HT concentrations rose from pre-
enge values similar to those of the control
nts to postchallenge values that were much
r, and the severity of duodenal histopatho-
al changes increased. Further studies will
quired to determine whether the raised tissue
s of 5-HT are due to hyperplasia or to hyper-
ity of EC cells or to both.

7655 CORRECTION OF COBALAMIN MALABSORPTION IN PANCREATIC INSUFFICIENCY WITH A COBALAMIN ANALOGUE THAT BINDS WITH HIGH AFFINITY TO R PROTEIN BUT NOT TO INTRINSIC FACTOR: IN VIVO EVIDENCE THAT A FAILURE TO PARTIALLY DEGRADE R PROTEIN IS RESPONSIBLE FOR COBALAMIN MALABSORPTION IN PANCREATIC INSUFFICIENCY. (Eng.) Allen, R. H.; Seetharam, B.; Allen, N. C.; Podell, E. R.; Alpers, D. H. (Washington Univ. Sch. Medicine, St. Louis, MO 63110). *J. Clin. Invest.* 61(6):1628-1634; 1978.

The hypothesis that the etiology of cobalamin (Cbl) malabsorption in pancreatic insufficiency is an inability to partially degrade R protein because of a lack of pancreatic proteases was tested by determining the ability of a nonradioactive Cbl analogue, bound with high affinity by R protein but not by intrinsic factor (IF), to correct the malabsorption of ^{57}Co-Cbl in three patients with pancreatic insufficiency. R protein bound the Cbl analogue known as cobinamide with affinities that were the same and only 14-fold lower than those for Cbl at pH 8 and pH 2, resp. Cobinamide was bound by IF with affinities that were 600,000- and 10,000-fold lower than those for Cbl at pH 8 and 2, resp. The addition of 125 pmol of nonradioactive cobinamide to 0.5 pmol of ^{57}Co-Cbl before being added to 1 pmol of R protein and 1 pmol of IF, markedly inhibited the ability of R protein to compete with IF for binding the ^{57}Co-Cbl. Similar results were obtained with freshly aspirated gastric juice. This change was essentially indistinguishable from that observed previously when R protein or R protein-^{57}Co-Cbl was incubated *in vitro* with trypsin. The p.o. administration of 100 nmol of nonradioactive cobinamide in Schilling tests was equivalent to trypsin in its ability to completely correct the malabsorption of 0.4 nmol of ^{57}Co-Cbl in the three patients with pancreatic insufficiency. The fact that both trypsin and nonradioactive cobinamide inhibit the ability of R protein to compete with IF for ^{57}Co-Cbl binding *in vitro*, and correct the malabsorption of ^{57}Co-Cbl in patients with pancreatic insufficiency *in vivo*, supports the hypothesis that the primary defect in Cbl absorption in this disease is an inability to partially degrade R protein because of a lack of pancreatic proteases.

LARGE INTESTINE

7663 A RANDOMIZED PROSPECTIVE EVALUATION OF ORALLY ADMINISTERED ANTIBIOTICS IN OPERATIONS ON THE COLON. (Eng.) Vargish, T.; Crawford, L. C.; Stallings, R. A.; Wasilauskas, B. L.; Myers, R. T. (Bowman Gray Sch. Medicine, Winston-Salem, NC). *Surg. Gynecol. Obstet.* 146(2):193-198; 1978.

The usefulness of orally administered antibiotics in the preoperative preparation of the intestine was investigated in colon specimens from 91 patients who underwent 3 days of mechanical preparation of the intestine and who were given one of three antibiotic groups the day before operation: neomycin and erythromycin base (NE), neomycin-phthalylsulfathiazole (NP), or neomycin (control, N). There were no significant differences among the three groups in terms of the types of operations performed. The baseline for comparison was established using samples from unprepared colon: 10^4-10^5 organisms/0.1 g tissue. By this standard 6/91 treated colons were bacteriologically unprepared (3 in the N group, 2 in the NE group, and 1 in the NP group), 25/91 colons were sterile (<10 organisms/0.1 g tissue; 10 in N, 10 in NE, and 5 in NP), and 60/91 were bacteriologically pr pared (10-10^3 organisms/0.1 g tissue, with no sig nificant differences among the groups). There was no association of any significant postoperati complication with any specific antibiotic preparation. The incidence of postoperative diarrhea was <7% and correlated better with the operative procedure than with the preoperative antibiotic. The wound infection rate ranged from 10% in the NE group to 12.5% in the N group, and these rates are extremely close to published national average

erations on the colon. The wound infections
ed in patients with bacteriologically pre-
colons, and 60% of them involved organisms
absent from the colon or present below
unting resolution (<10/0.1 g tissue) at the
f operation, indicating that adequate tissue
of the antibiotics had not been reached.
concluded that, while p.o. antibiotic
provides adequate intestinal antisepsis,
is possibly an advantage to parenteral
otic therapy in preparation for operations
adequate tissue antisepsis is desirable.

NEONATAL SMALL LEFT COLON SYNDROME. (Eng.)

Stewart, D. R.; Nixon, G. W.; Johnson, D.
don, V. R. (Univ. Kansas Medical Center, 39th
nbow Blvd., Kansas City, KS 66103). *Ann.*
86(6):741-745; 1977.

e reports, clinical findings, course, radio-
findings, pathology, and treatment of four
s with the neonatal small left colon syn-
SLCS) are presented. All infants had a
suggesting a low intestinal obstruction
the first 24-48 hr after birth. Three were
diabetic mothers who had toxemia or poly-
ios during pregnancy. These three infants
sistant fetal circulation syndrome hypo-
a and cyanosis shortly after birth. The
onal age of the four infants was between
40 weeks, and their weights ranged between
nd 4,500 g. Abdominal distention was pre-
nd the spontaneous passage of meconium was
. Plain abdominal roentgenograms showed
bowel in all four cases, and a pneumo-
eum was present initially in two cases.
enema examination showed a colon of sig-
tly reduced caliber from the anus to the
flexure, and there was generally a transi-
ne at the splenic flexure; this zone
ger than the one seen with Hirschsprung's
The colon proximal to the transition
dilated and distended with meconium. In
stance, the entire colon was readily filled.
gic examination in one patient showed an
ed ratio of small cells to multipolar gan-
lls. Three patients were operated upon be-
the presence of a pneumoperitoneum. Two
patients had cecal perforation, and both
symptoms of heart disease shortly after
The third patient had multiple ileal
ions in a marginally viable ileum. The
portion was excised and an ileostomy was
e patient survived. The fourth patient
omplications, and passed normal stools
g a second barium enema. These observa-
ggest that SLCS is not a benign disease
it can be fully cured by radiographic
enemas if detected early.

ABDOMINAL SCINTIPHOTOGRAPHY WITH
^{99m}TECHNETIUM-LABELLED ALBUMIN IN ACUTE
TESTINAL BLEEDING: AN EXPERIMENTAL STUDY

078

AND A CASE REPORT.

(Eng.) Miskowiak, J.; Munck, O.; Nielsen, S. L.; Andersen, B. (Bispebjerg Hosp., Bispebjerg Bakke, DK-2400 Copenhagen, Denmark). *Lancet* 2(8043):852-854; 1977.

A new diagnostic method for the detection of the bleeding site in acute gastrointestinal bleeding is described, and the method was tested in five volunteers and in one patient with acute bleeding. ^{99m}Technetium-labeled human serum albumin (1 mCi) is injected i.v., and the distribution of radioactivity in the abdomen is followed for 40 to 60 min by sequential scintiphotography. The site of simulated gastrointestinal bleeding was identified in all five volunteers. In the patient, a 91-yr-old man with severe bleeding from diverticula of the sigmoid colon, the method gave a correct estimate of the bleeding site and of its bleeding rate. These preliminary results suggest that this quick, noninvasive, easy technique may be useful in the diagnosis of gastrointestinal bleeding.

7666 VASCULAR DYSPLASIA OF THE RIGHT COLON: AN IMPORTANT CAUSE OF UNEXPLAINED GASTROINTESTINAL BLEEDING.

(Eng.) Broor, S. L.; Parker, H. W.; Ganeshappa, K. P.; Komaki, S., Dodds, W. J. (Medical Coll. Wisconsin, Milwaukee, WI). *Am. J. Dig. Dis.* 23(1):89-92; 1978.

The case of a 73-yr-old man with vascular dysplasia of the right colon is presented to emphasize the problems in diagnosis and discuss the value of different diagnostic methods as revealed in the literature for patients with chronic lower-gastrointestinal hemorrhage. The patient had a 3-yr history of frequent, intermittent black stools and occasional bright red blood in the stools, but there was no history of hematemesis, abdominal pain, anorexia, weight loss, or excessive alcohol consumption and no family history of any bleeding diasthesis. Numerous stool specimens were strongly guaiac-positive. The only other abnormal findings in routine studies were several diverticula of the left colon (by barium enema and pneumocolon examinations) and a small hiatal hernia (by roentgenographic examination of the upper gastrointestinal tract and a small bowel series). However, colonoscopic findings (a 2-cm in diameter, flat, reddish area in the ascending colon with irregular prominent blood vessels) and arteriographic findings (an area of irregular blood vessels in the upper ascending colon with early venous filling) were considered typical of vascular dysplasia. At laparotomy, a right hemicolectomy was performed, and the patient was well at 9-month follow-up. In chronic lower gastrointestinal hemorrhage, routine diagnostic studies may fail as much as 50% of the time, and negative findings at laparotomy may occur in as many as 70% of the cases. Arteriography and colonoscopy are extremely valuable diagnostic tools, especially in cases of vascular dysplasia, which are seldom within sigmoidoscopic reach and in which barium enema is often negative. The possibility of vascular dysplasia should be considered in any patient with chronic, obscure lower gastrointestinal bleeding.

7667 INTRALUMINAL CALCIFICATIONS IN THE SMALL BOWEL OF NEWBORN INFANTS WITH TOTAL COLONIC AGANGLIONOSIS.

(Eng.) Fletcher, B. D.; Yulish, B. S. (Univ. Hosp. Cleveland, University Circle, Cleveland, OH 44106). *Radiology* 126(2):451-455; 1978.

The cases of four neonates with total colonic aganglionosis in whom intraluminal calcifications were found in the small bowel are presented. Abdominal radiography demonstrated circular aggregations of small punctate calcific densities in the right lower quadrant and evidence of bowel obstruction. There was a microcolon in each case. The calcifications resembled those seen in small intestinal atresia and stenosis and are probably related to fetal intestinal stasis. Since in the 11 previously reported cases of intraluminal small intestinal calcifications the obstruction was not associated with meconium ileus or cystic fibrosis, intraluminal small bowel calcifications are likely to be associated with either small bowel atresia or total colonic aganglionosis.

7668 PSEUDOMEMBRANOUS COLITIS: PRESENCE OF CLOSTRIDIAL TOXIN.

(Eng.) Larson, H. E.; Price, A. B. (Clinical Res. Center, Watford Rd., Harrow, Middlesex HA1 3UJ, England). *Lancet* 2(8052/8053):1312-1314; 1978.

To identify the toxin involved in pseudomembranous colitis (PMC), the feces of 9 patients with histologically-proven PMC were studied and compared with results of similar studies in 18 other patients with other bowel diseases. Five of 9 and 2 of 18 patients had recently been treated with one or more of the antibiotics lincamycin, clindamycin, and ampicillin. A toxin was found in 9/9 PMC patients and in the 2/18 with antibiotic-associated nonspecific colitis; it was neutralizable by *Clostridium sordelli* antitoxin (detectable to titers of 1/100 or greater except for one case at 1/10,000) but not by gas gangrene antitoxin (a commercial preparation of *C. welchii*, *C. edematiens*, and *C. septicum* antitoxins), but the effect was morphologically different in the latter 2 patients. The tissue culture cytopathic effect (CPE) was produced by fecal extracts from all 11 patients and was neutralized in all cases by *C. sordelli* antitoxin; gas gangrene antitoxin did not neutralize the effect in the 9 PMC patients. When guinea pigs were inoculated with extracts from the feces of two PMC patients (tissue culture titers of 1/256 and 1/10,000), the results were comparable to those reported to follow inoculation with *C. sordelli* culture filtrates: the extract of lower titer produced a transient local edema; the more potent extract produced a massive, gelatinous, s.c. edema over the entire abdominal wall; and these animals died in 5-8 days after progressive weight loss and weakness. The PMC fecal toxin extract and *C. sordelli* extract both produced characteristic toxic CPE when inoculated into cultures of M.R.C. V cells. PMC fecal toxin was inactivated by heating at 56 C for 30 min, by incubation at pH 4 for 24 hr, and by incubation with specific antitoxin for 1 hr. These results compare well with previously obtained results for *C. sordelli* toxin. The results indicate that a specific clostridial toxin is closely associated
with PMC and that it is similar to *C. sordelli* in
many of its *in vivo* and *in vitro* properties.

7669 VALUE OF COLOSCOPY IN THE DETECTION OF SIGMOID MALIGNANCY IN PATIENTS WITH DIVERTICULAR DISEASE.

(Eng.) Glerum, J.; Agenant,
D.; Tytgat, G. N. (Wilhelmina Gasthuis, Eerste
Helmersstraat 104, Amsterdam Oud-West, Netherlands
Endoscopy 9(4):228-230; 1978.

The contribution of coloscopy to the diagnosis of
sigmoid carcinoma in 52 patients with diverticula
disease was evaluated. Coloscopy in 30 diverticu
disease patients without suspicion of malignancy
demonstrated diverticulosis/diverticulitis in 19
patients, diverticulosis plus polyp in 4, malig-
nancy in 2, and extrinsic compression in 2; the d
eased segment was not reached in 3 patients. Co-
loscopy in 22 diverticular disease patients sus-
pected of having co-existing malignancy of the si
moid colon revealed carcinoma in 10 patients, di-
verticulosis/diverticulitis in 3, diverticulosis
plus polyp in 1, and benign stenosis after resect
in 2; the disease segment was not reached in 6 pa
tients. Malignancy was subsequently demonstrated
by radiology in the two patients with stenosis af
resection and at surgical exploration in one of t
six patients suspected of having co-existing mali
nancy but not reached by coloscopy. There were n
false-positive or -negative cases. The results
demonstrate that coloscopy is useful for reaching
a correct diagnosis when concomitant malignancy o
the sigmoid colon is suspected in diverticular di
ease patients.

7670 SOLITARY DIVERTICULUM OF THE CAECUM AND ITS COMPLICATIONS.

(Eng.) Peltokallio
P.; Tykka, H.; Myllarniemi, H. (Second Dept. Sur-
gery, Univ. Helsinki, SF-00290 Helsinki 29, Finla
Ann. Chir. Gynaecol. 66(5):230-233; 1977.

The case reports of three patients with cecal div
ticula are presented. The patients were all men,
and two were younger than those usually having di
ticulitis of the colon (30 and 38 yr, resp.).
Acute appendicitis had been diagnosed preoperati
in all three cases in view of the symptoms, clin
findings, and laboratory findings. At laparotomy
the appendix was normal in each case. In the fi
patient, the diverticulum was situated 1 cm from
base of the appendix and was completely necrotic.
It was perforated and contained a fecolith, which
was probably responsible for the inflammation se
The diverticulum in the second patient was locat
4 cm from the base of the appendix on the latera
wall of the cecum. The third patient had a dive
ticulum surrounded by a large inflammatory, necr
mass. The diverticula were excised, and the mas
removed with a right-sided hemicolectomy. In vi
of the possibility that carcinoma may complicate
these diverticula, the authors support an aggres
approach to the treatment of inflammatory masses
the cecal wall.

NECROTIZING ENTEROCOLITIS (ISCHEMIC EN-
TEROPATHY) WITH THE SEQUEL OF COLONIC
SIA. (Eng.) Beardmore, H. E.; Rodgers, B. M.;
rbridge, E. (Montreal Children's Hosp., Mon-
l, Quebec, Canada). *Gastroenterology* 74(5,
1):914-917; 1978.

cases of acquired colonic atresia subsequent to
otizing enterocolitis (ischemic enteropathy) in
neonatal period are reported. The first pa-
t, a boy born at 33 weeks gestation, developed
toms of necrotizing enterocolitis at 5 days of
The patient had extensive gas in the bowel
and subsequently developed pneumoperitoneum.
aparotomy, extensive peritonitis was encountered
a perforation of the distal ileum. The dis-
d distal 10 cm of ileum and right colon were
cted, and an ileostomy was created. The patient
n tolerating p.o. alimentation, and a second
rotomy was performed with the intention of re-
ing intestinal continuity 11 weeks later. At
time, two areas of obstruction were found in
colon. A segment of proximal colon was re-
ed and showed marked edema and submucosal fi-
is consistent with previous neonatal ischemic
ropathy. A revision of the ileostomy and mu-
fistula was undertaken, and at 8 months of
a subtotal colectomy and ileoproctostomy was
ormed. The second patient, a boy born at 30
s of gestation, developed symptoms of necro-
ng enterocolitis on the day of birth. An ab-
nal radiograph revealed extensive pneumatosis
stinali with air within the portal venous sys-
Free air was also noted in the peritoneal
ty. At laparotomy, he was found to have se-
peritonitis and terminal ileal perforation.
terminal 12 cm of ileum and right colon were
cted, and an ileostomy was carried out. At 8
s of age, an ileotransverse colostomy was per-
ed, but the patient failed to pass stools per
um. Complete atresia of the colon in the re-
of the splenic flexure was encountered. An
descending colostomy was performed. Recogni-
of colonic atresia and other late sequelae
schemic enterocolitis becomes critical to the
essful outcome of these patients as survival
s increase.

ANORECTAL MYECTOMY IN TREATMENT OF ULTRA-
SHORT SEGMENT HIRSCHSPRUNG'S DISEASE:
RT OF 26 CASES. (Eng.) Scobie, W. G.; Mac-
ay, G. A. (Western General Hosp., Crewe Rd.,
burgh EH4 2XU, Scotland). *Arch. Dis. Child.*
):713-715; 1977.

rience with 140 children (ages 6 months-14 yr)
he period 1971-75 who were investigated for
tipation and soiling is presented. All chil-
had had chronic constipation from the 1st yr
ife; 35% had had continuous soiling. All were
stigated by anorectal manometry; 26 failed to
an inhibition response to rectal dilatation,
esting Hirschsprung's disease, and were treated
norectal myectomy. In 24 of the 26, the dis-
was confirmed histologically; 2 specimens
diagnostically unsuitable. In 21 myectomy
specimens, large abnormal nerve bundles and the absence of ganglion cells were found; 9/21 were totally aganglionic while 12/21 showed normal ganglia or a transitional zone of scattered ganglia at the upper end. Four required repeat myectomies to get above the aganglionic zone, with myectomy repeated twice in two. Three patients required anterior resection. In five myectomy specimens, large nerve bundles and muscle hypertrophy were seen. At follow-up, no patient was soiling, 17 patients achieved normal regular bowel movements after the initial myectomy, and the remaining 9 had normal function after repeat procedures. A diagnosis of Hirschsprung's disease should be considered in children with chronic constipation. An accurate neonatal history of bowel function and testing of anorectal pressure will aid the diagnosis. Anorectal myectomy is a simple procedure, often free of complications, that can be combined with anterior resection when the length of affected segment is too long for myectomy alone; these procedures offer effective palliation.

7673 PNEUMATOSIS CYSTOIDES COLI. (Eng.) Marshak, R. H.; Lindner, A. E.; Maklansky, D. (Mt. Sinai Sch. Medicine, City Univ. New York, New York, NY). *Gastrointest. Radiol.* 2(2):85-89; 1977.

The pathology, clinical features, roentgenographic features, and differential diagnosis of pneumatosis cystoides coli are reviewed. If the cysts are subserosal in location they are visible in the unopened specimen. On section, the bowel wall is honeycombed with gas cysts. The cysts are most often lined by a layer of endothelial cells. Diseases associated with pneumatosis cystoides coli include collagen disease, diabetes, colonic ischemia, inflammatory bowel disease, traumatic endoscopy, and polyp excision. Pneumatosis may be discovered as an incidental finding during examination for some other illness or abdominal cramps, diarrhea, and rectal bleeding may occur. Plain abdominal films may reveal grape-like radiolucent clusters along the contour of the colon and in the region of the mesentery. The clusters of air associated with pneumatosis cystoides coli can be readily distinguished from gas in abscess cavities because in pneumatosis there are discrete, sharply defined borders, and the cysts are distributed along the contours of the colon. The rectum is rarely involved, and the left colon is more frequently involved than the right. Barium enema examination reveals filling defects between the lumen, outlined by barium, and the outer margin of the bowel wall.

7674 RETRACTILE MESENTERITIS: INITIAL PRESENTATION AS COLONIC OBSTRUCTION. (Eng.) Williams, R. G.; Nelson, J. A. (Univ. Utah Medical Center, 50 N. Medical Drive, Salt Lake City, UT 84132). *Radiology* 126(1):35-37; 1978.

Two cases of apparent idiopathic mesenteric fibrosis in which the most significant problem was directly referable to the colon are presented. Both patients, a 54-yr-old woman and a 47-yr-old man, presented with signs and symptoms of bowel obstruction and a firm abdominal mass. Both had been relatively healthy prior to the onset of illness. Neither had a known family history of this or other fibrosing processes, or of exposure to allergens. There was no evidence of any coexistent neoplasm. In the first patient, a preoperative plain abdominal r[illegible] consistent with m[illegible] A barium enema examination revealed obstruction of the descending colon and apparent mucosal thumbprinting associated with a mass lesion. At operation, she was found to have multiple small and large bowel obstructions with progressive mesenteric colonic fibrosis and extensive fibrotic implants over the small bowel. A subtotal colectomy with an ileostomy and mucus fistula formation was carried out. Barium enema examination in the second patient revealed partial splenic flexure obstruction and mucosal thumbprinting. Because of near complete obstruction of the distal colon, a side-to-side transverse-to-distal sigmoid colostomy was carried out. The clinical history and findings of an obstructive lesion in the colon, where cancer is not necessarily suspected, should lead to a consideration of this entity for the radiographic diagnosis.

7675 VOLVULUS OF SIGMOID COLON IN CHILDHOOD--AN ENTITY TOO LITTLE REGARDED. (Ger.) Willmen, H. R.; Schultz-Stubner, A. (Chirurgische Klinik, Kreiskrankenanstalten Grevenbroich, 4048 Grevenbroich, W. Germany). *Aktuel. Chir.* 12(5):327-332; 1977.

The causes, symptoms, and treatment of sigmoid volvulus in children are described in connection with 12 cases observed since 1974. The patients included nine boys and three girls aged 9-15 yr. Abrupt body movement at gymnastics or play was the cause of volvulus in all cases. The volvulus manifested as sudden violent pain in the left lower abdomen, causing local tenderness and defense and hemiflexion of the left hip and knee. The transverse sigmoid coil was palpable rectally. Two-thirds of the patients developed vertigo and nausea. The patients showed a tendency to obstipation, but complete intestinal shock with hyperthermy and toxic dyspnea did not occur. The therapy was conservative in 11 cases; it consisted of bimanual detorsion (bringing immediate relief to 7 cases) and of contrast enema in 2. Bimanual detorsion can be regarded successful only if the patient has no pains after massive defecation. Operative detorsion and mesosigmoidopexy at the lateral abdominal wall was necessary in one case. Sigmoidopexy is always indicated in the case of recurrent volvulus.

Ulcerative Colitis

SKIN TEST REACTIVITY IN INFLAMMATORY
BOWEL DISEASE IN THE UNITED STATES AND
IOSLOVAKIA. (Eng.) Thayer, W. R., Jr.; Fixa,
Komarkova, O.; Charland, C.; Field, C. E. (Rhode
id Hosp., 593 Eddy St., Providence, RI 02902).
. Dig. Dis. 23(4):337-340; 1978.

nts with inflammatory bowel diseases and
ols in the United States and in Czecho-
kia were tested with five skin test anti-
at two different dilutions to elicit some
nce of anergy. *Candida* was first injected as
,000 dilution; if this initial skin test was
ive, a second strength dilution (1:100) was
administered. Mumps was injected intradermally
complement-fixing units, and no second strength
en was used. Purified protein derivative (PPD)
njected intradermally at 1 US unit, and if
was negative, 5 US units were injected. Strep-
ase-streptodornase (SK-SD) was first used as
bination of 100 U streptokinase and 25 U of
todornase. If the response to the first
gth was negative, a second injection of 400
SK and 100 U of SD was injected. Trichophytin
njected first as a 1:100 dilution, and the
d strength was 1:30. No skin test anergy was
to exist when patients were compared to
ols. The incidence of PPD responsiveness
e Czechoslovakian subjects was greater than
e United States subjects ($p<0.01$ for patients
<0.001 for controls). When reactivity to
-strength injections only was assessed, no
ficantly diminished responsiveness was ap-
t between the two populations or between any
nt group and its controls. Comparisons based
e number of individuals responding positively
1, 2, 3, 4, or 5 out of 5 skin test antigens
strated that no significant differences were
ntered between the two populations or between
atient group and its controls. There is no
nce of anergy as assessed by diminished skin
reactivity in patients with inflammatory bowel
ses.

UROLITHIASIS IN CHRONIC INFLAMMATORY
BOWEL DISEASE. (Eng.) Knudsen, L.;
ssen, H.; Fleckenstein, P.; Pedersen, E. B.;
n, S. (Rigshospitalet, DK-2100, Copenhagen,
rk). *Scand. J. Gastroenterol.* 13(4):433-436;

rospective clinical study of the occurrence
inary calculi was analyzed in 494 consecutive
artially selected patients with chronic
mmatory bowel disease (CIBD) to elucidate
echanism of stone formation. By restrict-
he analysis only to patients studied by
pyelography (IP), the material was cur-
l to 140 patients with Crohn's disease (CD)
3 with ulcerative colitis (UC). Urolithiasis
roved by IP in 18/140 patients with CD and
with UC, with no significant difference be-
the two groups or by sex in either group.
There were no significant correlations of urolithiasis to duration of disease, history of ileostomy, site of lesion, or extent of disease. Urolithiasis was significantly correlated to a history of small bowel resection ($p<0.01$), most strongly so in those with resections ≥ 50 cm in length. Only among patients with UC was urolithiasis more common among the steroid-treated than among the nonsteroid-treated ($p<0.01$). Urolithiasis was also significantly increased in patients with urinary tract obstruction ($p<0.05$ for CD, $p<0.01$ for UC). The results are consistent with the hypothesis that the hyperabsorption of oxalate following ileal resection plays an important role in stone formation. The essential role of local factors in stone formation is apparent from the increased incidence of calculi in patients with urinary tract obstruction. The few and negligible symptoms of and sequelae to urolithiasis in CIBD encourage a conservative attitude.

7724 THE DILEMMA OF PRESERVATION OF THE RECTUM: RETENTION OF THE RECTUM IN COLECTOMY FOR INFLAMMATORY DISEASE OF THE BOWEL. (Eng.) Mavroudis, C.; Schrock, T. R. (Dept. Surgery, Univ. California, San Francisco, CA). *Dis. Colon Rectum* 20(8):644-648; 1977.

The records of 100 consecutive patients who underwent total abdominal colectomy, proctectomy, or both for inflammatory bowel diseases at one hospital between 1966 and 1976 are reviewed to determine the validity of the current policy in which the rectum is retained and anastomosed to the ileum only when the rectum is not involved by inflammatory disease. The rectum was preserved at the time of colectomy in 58 patients, but only 18 had normal rectums at the initial operation. Only nine patients underwent ileoproctostomy, six primarily and three secondarily. Only three patients are living with ileoproctostomy; among the remaining patients, one died of colonic cancer, three subsequently underwent proctectomy, and two have a defunctionalized rectum with ileostomy. These results indicate that when the rectum is involved by inflammatory disease, it is advisable to do a proctectomy to eliminate the risk of cancer and to restore patients to productive lives.

7725 TOTAL COLECTOMY AND MUCOSAL PROCTECTOMY WITH PRESERVATION OF CONTINENCE IN ULCERATIVE COLITIS. (Eng.) Martin, L. W.; LeCoultre, C.; Schubert, W. K. (Coll. Medicine, Univ. Cincinnati, Cincinnati, OH). *Ann. Surg.* 186(4):477-480; 1977.

A technique for preserving rectal continence in patients undergoing total colectomy for chronic ulcerative colitis is described, and its results in 17 patients are presented. Intensive medical management, total parenteral alimentation, steroid therapy, establishment of a preliminary diverting ileostomy with subtotal colectomy, or a combination of these measures are required to insure that the rectal mucosa is free of gross disease at the time of operation. At surgery, the rectal mucosa is removed, but all the anorectal musculature is preserved. Total colectomy is performed, and the terminal ileum is then placed inside the retained muscular wall of the rectum and anastomosed to the anus. Satisfactory results were obtained in 15 patients, and no patient died. Thirteen patients are completely continent, and the other two have proximal ileostomies that have not yet been closed. The two failures were both due to pelvic sepsis, emphasizing the need for thorough rectal irrigation at the time of operation. All patients had frequent, watery stools for several weeks following surgery, and as long as 6 or 12 months were required for adaptation. Only four patients still have diarrhea, but this is satisfactory for the stage after operation. Ten patients, including the two failures, developed postoperative complications. These included wound infections (5 patients) due to operative rectal perforation, bleeding from the superior hemorrhoidal artery (1 patient), small bowel obstruction due to adhesions (3 patients), and "cuff abscess" (3 patients). The latter was an abscess forming inside the rectal cuff between it and the wall of the ileum and in the absence of anastomotic leak. All three patients developed stricture requiring release or dilatation. The results in these patients suggest that it is possible to perform a total colectomy with mucosal proctectomy and preserve anorectal continence.

7726 THE PROGNOSIS OF CARCINOMA OF THE COLON AND RECTUM COMPLICATING ULCERATIVE COLITIS. (Eng.) Hughes, R. G.; Hall, T. J.; Block, G. E.; Levin, B.; Moossa, A. R. (Pritzker Sch. Medicine, Chicago, IL). *Surg. Gynecol. Obstet.* 146(1): 46-48; 1978.

To test the hypothesis that the prognosis of colonic carcinoma in association with ulcerative colitis is poor, the survival rates and the tumor spread in 29 patients with ulcerative colitis and colonic carcinoma were compared with those in matched controls with carcinoma but without colitis. There were a total of 33 tumors in the 29 patients with colitis. The 5-yr survival rate in the group with colitis was 55.1%, and that in the patients without colitis was 46.9%, which was not a statistically significant difference. The spread of tumor as measured by penetration of the intestinal wall and by adjacent nodal invasion for the two patient groups showed that 30.5% of the carcinomas in patients without colitis had the same degree of spread as did those in patients with colitis; 44% of the carcinomas in patients without colitis had a more extensive spread and 25.5% of the carcinomas in patients without colitis exhibited less invasion than did carcinomas in patients with colitis. Patients with colitis and colonic carcinoma did not have more extensive penetration of the intestinal wall or more frequent nodal invasion than did those with carcinoma without colitis. In fact, the tumors arising in previously normal intestine appeared to exhibit a tendency for a greater degree of spread than did those tumors arising from an inflamed intestine ($p<0.001$). Tumors in patients with ulcerative colitis exhibit no greater invasiv ness and are associated with the same overall survival rate as those occurring in a population without colitis.

7727 SALT-LOSING DIARRHOEA IN IDIOPATHIC PROCTOCOLITIS. (Eng.) Caprilli, R.; Sopran N.; Colaneri, O.; Levi Della Vida, M.; de Magistri L. (Second Medical Clinic, Univ. Rome, Policlinico Umberto I, 00100 Rome, Italy). *Scand. J. Gastroenterol.* 13(3):331-335; 1978.

The fecal chloride, sodium, and potassium outputs were studied in 14 patients with active idiopathic proctocolitis to establish a relationship between fecal electrolyte output and acid-base balance data. Seven ileostomized patien and eight healthy subjects served as controls. Mean sodium output was significantly higher in bot ileostomy patients ($p<0.05$) and in the patients wi proctocolitis ($p<0.05$) than in the normal subjects The mean chloride excretion was also significantly higher in both patient groups ($p<0.01$), and high chloride excretion was seen in all but two patient with proctocolitis. Potassium excretion was not significantly different in the controls and proctocolitis patients, but it was significantly lower than controls in the ileostomized patients ($p<0.0$ It appears that the colons of patients with proctocolitis have an impaired capacity to absorb chl ide and sodium but retain the ability to secrete potassium. Intestinal sodium, chloride, and wate loss may be regarded as a salt-losing diarrhea an may account for the metabolic alkalosis commonly found in proctocolitis.

PANCREAS

737 PERCUTANEOUS FINE NEEDLE ASPIRATION BIOPSY OF THE PANCREAS FOLLOWING ENDOSCOPIC ETROGRADE CHOLANGIOPANCREATOGRAPHY. (Eng.) o, C. S.; McLoughlin, M. J.; McHattie, J. D.; ao, L. C. (Toronto General Hosp., Toronto, Onario, Canada). *Radiology* 125(2):351-353; 1977.

arly experience in combining percutaneous fine eedle aspiration biopsy with endoscopic retrograde holangiopancreatography (ERCP) in the diagnosis f pancreatic cancer is reported. The combined rocedures were performed in nine patients with uspected pancreatic malignancies. The ERCP dignosis was carcinoma in eight of the nine paients and localized stenosis of the body of the ancreas in the ninth patient. Biopsy confirmed he diagnosis in seven of the eight patients with arcinoma and provided a diagnosis of pancreatitis n the ninth patient. ERCP is an accurate method or diagnosing pancreatic cancer, and fine needle spiration biopsy can confirm this diagnosis afely and easily.

738 ANNULAR PANCREAS: A NEW CLASSIFICATION AND CLINICAL OBSERVATIONS. (Eng.) Johnton, D. W. B. (Westminster Hosp., London, Ontario 5A 4S2, Canada). *Can. J. Surg.* 21(3):241-244; 978.

even cases of annular pancreas are described in hich the diagnosis was confirmed at autopsy or peration. Annular pancreas appears to comprise wo distinct subtypes not previously recognized. In type 1 (extramural), the ring of pancreatic tissue lies on the muscular wall of the duodenum and is covered by a thin layer of peritoneum. A definite plane of cleavage may be established between the annulus and the duodenum. There is always a main duct that sweeps dorsally and to the right around the duodenum to empty into the common bile duct or into the main pancreatic duct. Type 1 is usually associated with a dilated duodenum or megalobulbus and produces symptoms of high intestinal obstruction. In type 2 (intramural), the pancreatic tissue lies buried in the wall of the duodenum; any attempt to dissect out the annulus results in opening the lumen of the duodenum. There is no main ductal system, but rather a network of small canaliculi. Type 2 is usually associated with duodenal ulceration, and the clinical symptoms are due to the ulcer rather than to the annulus. Surgical treatment of type 1 is most successful if a simple bypass procedure is carried out. Surgical treatment of type 2 is subtotal gastrectomy with or without vagotomy.

7739 PANCREATIC ASCITES: REPORT OF TWO CASES. (Eng.) Aitchison, J. M.; White, J. A. M. (Addington Hosp., Durban, South Africa). *S. Afr. Med. J.* 52(24):982-984; 1977.

Two cases of pancreatic ascites are reported in which endoscopic retrograde and operative pancreatography were used to demonstrate the source of leakage from the duct system. The first patient was an alcoholic 34-yr-old man with a pancreatic pseudocyst. At laparotomy, contrast material was injected into the pseudocyst and appeared to leak into the general peritoneal cavity through the gastroepiploic foramen. A large retention cyst was demonstrated in the head of the pancreas, but no communication with the pancreatic duct system was found. A Roux-en-Y pancreaticojejunostomy was employed to drain both the retention cyst and the pseudocyst. The second patient was a 37-yr-old woman with recurrent severe abdominal pain, vomiting, diarrhea, weight loss, and ascites. Endoscopic retrograde pancreatography showed gross distortion of the gastric antrum and pylorus but no intrinsic lesion of the stomach or duodenum. Cannulation of the pancreatic duct and injection of contrast material demonstrated a stricture of the distal main pancreatic duct and leakage of contrast material through a fistula at the stricture into the lesser sac. The distal pancreatic duct system appeared to be grossly distorted with an intrapancreatic abscess cavity. A preoperative diagnosis of pancreatitis of unknown etiology with ascites secondary to leakage from an obstructed duct system was made. At laparotomy, dense adhesions were found around the distal pancreas, which was distorted and fibrosed. An abscess cavity was found in relation to the tail of the pancreas. The exact site of leakage from the duct system could not be identified, but the transitional zone from normal to abnormal pancreatic tissue was immediately to the left of the portal vein. The patient is asymptomatic 1 yr following distal pancreatectomy and splenectomy.

7740 INDOMETHACIN-RESPONSIVE PANCREATIC CHOLERA.

(Eng.) Jaffe, B. M.; Kopen, D. F.; DeSchryver-Kecskemeti, K.; Gingerich, R. L.; Greider, M. (Washington Univ. Sch. Medicine, 4960 Audubon Ave., St. Louis, MO 63110). *N. Engl. J. Med.* 297 (15):817-821; 1977.

The case of a patient with the Verner-Morrison syndrome whose symptoms rapidly abated after the institution of indomethacin therapy is presented. The patient, a 67-yr-old woman, had a 9-yr history of diarrhea. She noted a 7-kg weight loss and weakness during the 3 months before she was hospitalized. A 1-week trial of p.o. indomethacin (25 mg/8 hr) resulted in marked diminution of stool volume and frequency, with attainment of essentially normal bowel habits. At laparotomy, a well-circumscribed tumor of the tail of the pancreas was resected. The patient is asymptomatic 3 months after surgery and has not required indomethacin. The plasma prostaglandin E, prostaglandin F, vasoactive intestinal peptide (VIP), gastrin, and human pancreatic polypeptide (HPP) levels were 977, 39, 82, 44, and 631 pg/ml on admission; with indomethacin treatment, these levels were 311, 45, 48, 41, and 621 pg/ml, and the postoperative levels were 310, 76, 129, 41, and 377 pg/ml, resp. The levels in the tumor were 52.5, 2.3, 7.7, 0.3, and 830 ng/g, and the levels in the pancreas were 3.5, 7.6, 1.5, 0.5, and 11,370 ng/g, resp. These results show that VIP or HPP was not involved in the pathogenesis of this patient's symptoms; prostaglandin E was clearly implicated in this patient.

7741 RAPID DEVELOPMENT AND SPONTANEOUS REGRESSION OF PANCREATIC PSEUDOCYSTS DOCUMENTED BY ULTRASOUND.

(Eng.) Sarti, D. A. (Univ. California at Los Angeles Center for the Health Sciences, Los Angeles, CA 90024). *Radiology* 125(3): 789-793; 1977.

Three cases of pancreatic pseudocyst were followed serially by ultrasound examination. In the first case, the development of a pancreatic pseudocyst was well-documented by serial ultrasound examinati No pseudocyst was present 6 days prior to the documentation of a large cyst found following an acute episode of abdominal pain markedly different from any pain noted previously during the hospital admission. The episode was initially felt to be due to acute exacerbation of the patient's pancreatitis, but in retrospect it coincided with the development of the pseudocyst. The patient underwent surgery 24 days after the last normal ultrasound study was done and 18 days after the pseudocyst was first documented. The pseudocyst probably developed at the time of the acute episode. This case indicates that pseudocysts of a relatively large size can arise quite rapidly and that acute abdominal pain suspected of being an exacerbation of underlying pancreatitis may indicate impending pseudocyst development. The wall of this pseudocyst was found to be mature enough to anastomose to the jejunum at the time of surgery. The maximum length of time for this maturation to have occurred was 3.5 weeks, with a minimal possible time of less than 3 weeks. In the other two patients, the pseudocysts regressed spontaneously. Pancreatic abscess could not be ruled out in these cases, but the patients did not manifest severe leukocytosis or fever and received no antibiotic therapy. The ultrasound findings of pancreatic abscess usually show thick more irregular walls than those demonstrated in these patients. One patient had been scheduled for surgery until the ultrasound examination revealed a decrease in the size of the cyst. She was followed by ultrasound and treated medically with successful results. The other patient's pseudocyst gradually increased in size until it reached 4 cm. She subsequently develope an acute episode of abdominal pain and, after thi ultrasound no longer showed the pseudocyst. Thes cases illustrate that presently held convictions concerning the evolution and treatment of pancreatic pseudocysts must be reevaluated.

AMYLASE THERMOLABILITY: ITS APPLICATION IN THE DIAGNOSIS OF ACUTE PANCREATITIS AND
REATIC PSEUDOCYSTS. (Eng.) Donaldson, L.
Brodie, M. J.; Joffe, S. N.; McIntosh, W.
J. Meyer Memorial Hosp., Buffalo, NY). *Surg.*
m 28:444-445; 1977.

usefulness of a thermolability technique for
accurate identification of serum amylase iso-
mes was investigated using sera from 22 pa-
ts with acute pancreatitis, 12 with acute par-
is, 14 with resolved pancreatitis, 9 with
reatic pseudocyst, and 23 healthy controls.
percentage thermolabile amylase in each of
e groups was 84 ± 13, 83 ± 12, 55 ± 10, 79 ±
and 44 ± 10, resp. These findings are con-
ent with an outpouring of salivary or pan-
tic (i.e., heat-labile) amylase during in-
matory processes of the parotid glands or
reas. As pancreatitis resolves, the normal
l of thermolability (44 ± 10%) is again ap-
ched (55 ± 10%). Amylase thermolability is
ick and simple test that appears to increase
clinical application of the serum amylase
l as a diagnostic tool in acute pancreatitis
pancreatic pseudocyst.

7752 DEATH FROM ACUTE PANCREATITIS: M.R.C. MULTICENTRE TRIAL OF GLUCAGON AND APROTININ. (Eng.) Welbourn, R. B.; Armitage, P.; Gilmore, O. J. A.; MacKay, C.; Trapnell, J. E.; Williamson, R. C. N.; *et al.* (Northwick Park Hosp., Watford Rd., Harrow, Middlesex, HA1 3UJ, England). *Lancet* 2(8039):632-635; 1977.

The influence of glucagon and aprotinin on the death rate from acute pancreatitis was studied in a randomized double-blind multicenter trial, which included 257 patients with a serum amylase level of at least 2,000 IU/l. The drug doses were: aprotinin, 500,000 U i.v. immediately followed by 300,000 U by i.v. infusion 6-hourly for 5 days and glucagon, 2 mg, i.v., immediately followed by 2 mg by i.v. infusion 6-hourly for 5 days. The death rate in the whole group was 11%. The differences between treatment groups were not statistically significant (χ^2=0.26, 0.8<p<0.9). Neither the etiological factors in the development of pancreatitis, nor the age or sex of the patient influenced the death rate significantly. Active treatment did not improve the chances of survival in patients in whom there was no history of a previous attack, and active treatment failed to influence the death rate in those patients who did not have surgical treatment. The results indicate that, in the doses used, neither drug diminishes the risk of death in acute pancreatitis.

7753 LIPID ALTERATIONS IN ACUTE PANCREATITIS. (Eng.) Lazaro, E. J.; Bose, A. K.; Spraggins, R.; Dispenziere, B. R. (Martland Hosp., 65 Bergen St., Newark, NJ 97107). *Can. J. Surg.* 21(3): 270-271; 1978.

Important and previously unreported changes in carbon-16 and carbon-18 fatty acids of the blood in acute experimental pancreatitis in dogs and acute pancreatitis in humans are described. Acute pancreatitis was induced by the Pfeffer closed duodenal loop in 7 dogs; in the control animals, conditions that clinically resemble acute pancreatitis were induced: celiotomy (3 dogs), bilateral ureteral ligation (3), duodenal perforation (3), strangulation obstruction (4), strangulation obstruction with manipulation of the common bile duct (3), and hemipancreatectomy (2). Venous blood samples were obtained at 0, 3, 6, and 9 hr after each operation, and the animals were sacrificed for autopsy. Mass spectroscopy and gas chromatography were used to study the blood fatty acid profile in these animals and in three patients with acute pancreatitis and five with nonpancreatic acute abdominal disease (controls). A marked increase in the concentration of fatty acids with mono-unsaturation in both carbon-16 and carbon-18 chains and with di-unsaturation in the carbon-18 chains was observed. The amount of carbon-16 unsaturated acids increased from about 15% of the saturated carbon-16 acids in controls to up to 20 times that amount in acute pancreatitis.

7754 ACUTE PANCREATITIS AND SEROLOGICAL EVIDENCE OF INFECTION WITH Mycoplasma pneumoniae. (Eng.) Freeman, R.; McMahon, M. J. (General Infirmary, Leeds, England). *Gut* 19(5):367-370; 1978.

Paired serum samples from 27 patients with acute pancreatitis were examined for evidence of infection with *Mycoplasma pneumoniae, Coxiella burneti,* influenza viruses types A and B, adenovirus, chlamydia subgroup B, mumps virus, and Coxsackie viruses group B, types 1-6 because previous studies have suggested that some cases of pancreatitis are associated with viral agents or with *M. pneumoniae.* Evidence of infection with Coxsackie viruses group B was found in three patients and of infection with *M. pneumoniae* in nine patients. No evidence of *M. pneumoniae* was found in any of the three patients with evidence of Coxsackie virus infection. The results support those previously reported in which a substantial proportion of patients with acute pancreatitis have serological evidence of *Mycoplasma* infection, but this link must be further investigated.

7755 RESPIRATORY COMPLICATIONS OF ACUTE PANCREATITIS. (Ger.) Baumann, C.; Akovbiantz, A.; Danczkay, Z.; Heinzelmann, F. (Kantonsspital, Ramistrasse 100, CH-8091 Zurich, Switzerland). *Helv. Chir. Acta* 44(4):509-513; 1977.

Severe respiratory complications were seen in 12 patients with acute hemorrhagic pancreatitis. Pancreatitis was due to lithiasis in four patients, to alcoholism in three, and the etiology was not ascertained in one. Four patients had postoperative pancreatitis: one after cholecystectomy, two after surgery on the common bile duct, and another after total gastrectomy. Most blood gas parameters and radiological changes of the thorax became pathological within the first 3 days of pancreatitis. Despite intensive care, 11 patients died, including those with postoperative pancreatitis. The findings indicate the importance of the detection of early hypoxia, which should be treated as soon as possible by sufficient oxygenation. If the arterial pO_2 does not improve, endotracheal intubation should be performed without undue delay.

7756 ATYPICAL PANCREATIC PSEUDOCYSTS. (Eng.) Oleszchuk-Raszke, K.; Domanski, Z.; Niezabitowski, K. (Pomeranian Medical Acad. in Szczecin, Szczecin, Poland). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 128(4):464-468; 1978.

Three cases of atypical pancreatic pseudocyst, occurring in the course of chronic pancreatitis are presented. The cysts, formed by means of fistulization along the lienorenal ligament, were diagnosed on the basis of arteriography and confirmed surgically. In case I, splenomegaly was present, and selective celiac and superior mesenteric arteriography showed an avascular mass (15 x 8 cm) in the external part of the spleen. The removed intrasplenic pseudocyst was filled with yielded fluid (diastase determination, 8,888 Wohlgemuth's U; lipase determination, 0.6 U/ml). In case II, a palpable mass in the left upper quadrant with posterior displacement of the stomach was shown by selective splenic arteriography to be an avascular mass 8 cm in diameter. Indirect splenoportography showed splenic vein obstruction, one of the first symptoms of pancreatic pseudocyst in the hilus of the spleen. The cyst with the distal part of the pancreas and the spleen were resected. In case III, a palpable mass developed in the left upper quadrant 4 months after chronic pancreatitis and obstruction of the splenic vein had been diagnosed. During arteriography, there appeared a regular, oval blush (7 x 9 cm), characteristic of bleeding into the cyst, in the region of the tail of the pancreas. The vascular blush increased in intensity and persisted 20 min. The authors conclude that the possibility of an atypical pancreatic pseudocyst should be considered in all cases of chronic pancreatitis. Radiological diagnosis of such a cyst is possible by means of selective celiac, splenic, and superior mesenteric arteriography, and early diagnosis is vital to a successful outcome.

7757 THE PANCREAS AND IMMUNOGLOBULINS. II. IMMUNOGLOBULIN LEVELS IN THE PANCREATIC

RETIONS OF PATIENTS WITH CHRONIC PANCREATITIS.
;.) Soto, J.; Aufses, A. H., Jr.; Dreiling,

, 100th St. and Fifth Ave., New York, NY 1002
J. *Gastroenterol.* 67(6):561-564; 1977.

etermine whether immunologic participation
hronic pancreatitis might explain the per-
ence and progressive nature of the disease,
secretory patterns of immunoglobulins in 15
ents with chronic pancreatitis were compared
those of patients without pancreatic disease.
mean IgG, IgA, and IgM levels in the patients
28.5 ± 24.8 mg/dl, 17.5 ± 11.4 mg/dl, and
± 1.1 mg/dl, resp. These levels were not
ificantly different from those in the patients
out pancreatic disease (21.44 ± 16, 7.20 ±
and 1.5 ± 0.97 mg/dl, resp.). However, in
ents who stopped drinking but nevertheless
on to develop chronic pancreatitis, higher
normal pancreatic IgG and IgA levels were
d, thereby implying an immunologic mechanism
he cause of progressive pancreatic abnormality.

PANCREATITIS AND PANCREATIC CARCINOMA,
DIAGNOSED BY PEROPERATIVE FINE NEEDLE
RATION BIOPSY. (Eng.) Hastrup, J.; Thommesen,
Frederiksen, P. (Municipal Hosp., Aarhus, Den-
). *Acta Cytol.* 21(6):731-734; 1978.

cytologic pattern was evaluated in 37 benign
malignant pancreatic lesions in a series of
needle aspiration biopsies. Malignant cells
correctly identified in all 19 cases of cancer
pt 2 highly differentiated adenocarcinomas; the
gnant cells identified came from 17 adenocar-
mas, 1 fibrosarcoma, and 1 lymphoma. Since
ammatory cells, debris, and atypical cells were
d in both the benign (i.e., pancreatitis) and
malignant tissue, the cytodiagnosis of pancrea-
s was not reliable.

LIVER AND BILIARY TRACT

7781 HEPATIC SINUS CELLS (ENDOTHELIAL CELLS, KUPFFER CELLS, ITO CELLS, PIT CELLS WITH ENDOCRINE GRANULES): FUNCTIONAL CHANGES AND LESIONS IN HUMAN LIVER DISORDERS. (Fre.) Albot, G.; Parturier-Albot, M.; Reynes, P. (8, rue des Saints-Peres, 75007 Paris, France). *Ann. Gastroenterol. Hepatol.* 14(1):5-34; 1978.

An extensive review is presented of the role of the four cells found in the hepatic sinuses, but particularly the Kupffer cell, which is part of the mononucleated phagocyte system (reticuloendothelial system). The changes in the hepatic sinus cells observed in the human in the course of liver pathology such as excretory cholestasis, toxic hepatitis, viral hepatitis, and granulomatous hepatitis are described from their histological and functional aspects. The Kupffer cells have a dual function: (1) phagocytosis and intracellular digestion si
to that of other phagocytes and (2) specific pe
meability, permitting transfer to the blood of
stances metabolized in the hepatocytes.

7782 KIDNEY FAILURE DURING LIVER DISEASE.
SIGNIFICANCE OF ENDOTOXINS. (Ger.)
kinson, S. P. (King's Coll. Hosp. and Medical Sc
Denmark Hill, London, SE 5, England). *Z. Gastr*
enterol. 15(11):663-669; 1977.

The pathological mechanism of acute renal failu
occurring during liver cirrhosis, fulminant hep
failure due to acute viral hepatitis, halothane
hypersensitivity, or overdose of paracetamol is
discussed. Acute renal failure may occur with
tubular necrosis or without it (functional renal

ure). The underlying pathophysiological change
n intense renal and intrarenal vasoconstriction.
ence is presented that the vasoconstriction is
to systemic endotoxemia resulting from the
ure of the liver to filter out endotoxins ab-
ed from the gastrointestinal tract. Endotoxins
e renal vasoconstriction and glomerular and
tubular fibrin deposition by activating intra-
l coagulation. Acute tubular necrosis is in-
reted as the consequence of fibrin deposition;
osis of the renal cortex may also occur in
ous cases. In case of pronounced vasoconstric-
, acute tubular necrosis may also be the con-
ence of tissue anoxia. Acute renal failure
in obstructive jaundice has also been related
ndotoxemia, but, in contrast to cirrhosis and
inant hepatic failure, this is usually due to
ssociated gram-negative infection, and the
l failure almost invariably has the features
cute tubular necrosis. The findings indicate
the nature of the renal failure depends on
balance between vasoconstriction and fibrin
sition, which may be profoundly altered by
underlying liver disease.

HAPTOGLOBIN IN VARIOUS DISEASES: A REVIEW.

(Ger.) Heilmann, E. (Medizinische
klinik, Westfalische Wilhelms-Universitat, West-
3, D-44 Munster [Westf.], W. Germany). *Folia
atol. (Leipz.)* 104(5):608-618; 1977.

ies and observations on changes in the serum
oglobin (Hp) levels in various diseases are re-
ed. Increased serum Hp levels were found in
matoid arthritis, aplastic anemia, cholestasis,
alignant peptic ulcer, ulcerative colitis,
etic angiopathy, and during estrogen therapy
the use of oral contraceptives. Hemolysis,
loblastic anemia, and hepatocellular diseases
accompanied by reduced serum Hp levels. The
n Hp level is usually reduced in acute and
nic lesions of the liver parenchyma; there seems
e a correlation between the extent of the le-
and the serum Hp level. These findings sug-
that a disorder in protein synthesis is the
e of reduced Hp levels in inflammatory hepatic
esses. The determination of the serum Hp levels
elevant for the diagnosis of liver cirrhosis;
necrotic and portal cirrhoses are usually ac-
anied by subnormal Hp levels, while normal val-
are found in biliary cirrhosis. Especially
Hp levels are found in cirrhosis associated
splenomegaly. The Hp level is lowest in cryp-
nic portal cirrhosis, juvenile cirrhosis, and
chromatosis. The serum Hp level is usually
al in secondary liver carcinoma.

ULTRASTRUCTURAL MORPHOMETRIC INVESTIGATIONS ON LIVER BIOPSIES. THE INFLUENCE
RAL CONTRACEPTIVES ON THE HUMAN LIVER.

(Ger.)
, K.; Themann, H.; Verhagen, A. (Lehrstuhl
Medizinische Cytobiologie, Westring 3, D-4400
ter, W. Germany). *Arch. Gynaekol.* 223(3):205-
1977.

biopsy specimens from 12 healthy women who
had been using oral contraceptives (lynestrenol or ethinyl estradiol) for 2-76 months were investigated morphometrically according to Weibel's method. The stereological data obtained were compared with standard values for normal human liver biopsies. The volume density of the lysosomes per ml of hepatocytes showed a pronounced, significant ($p<0.001$) increase in the biopsy specimens from the probands. The cytoplasm was slightly enlarged, and the size of the cell nuclei reduced. The other parameters showed no substantial ultrastructural alterations of the liver following the use of hormonal contraceptives. Functional alteration cannot, however, be excluded.

7785 BENIGN HEPATIC LESIONS IN WOMEN TAKING ORAL CONTRACEPTIVES.

(Eng.) Davis, T. J.; Berk, R. N. (Presbyterian Hosp., 8200 Walnut Hill Lane, Dallas, TX 75231). *Gastrointest. Radiol.* 2(3):213-219; 1977.

Four cases of benign hepatic cell lesions in young women taking oral contraceptives are reported. The patients ranged in age from 23 to 41 yr and had taken oral contraceptives for 4 to 7 yr. In the first patient, focal nodular hyperplasia was discovered at exploratory laparotomy after a midepigastric abdominal mass was palpated during a routine physical examination. In another patient, focal nodular hyperplasia was found incidentally at pelvic exploration for a suspected ovarian tumor. The other two patients presented with abdominal pain and intraperitoneal bleeding; both patients had hepatic adenomas, and one also had focal nodular hyperplasia and a retention cyst. Angiography and radionuclide scanning aided in localizing and estimating the size of the liver lesions.

7786 IATROGENIC LIVER ABSCESSES: A COMPLICATION OF HEPATIC ARTERY LIGATION FOR TUMOR.

(Eng.) Jochimsen, P. R.; Zike, W. L.; Shirazi, S. S.; Pearlman, N. W. (Univ. Hosp., Iowa City, IA 52242). *Arch. Surg.* 113(2):141-144; 1978.

A review of six case histories of patients who developed intrahepatic pyogenic abscesses following therapeutic hepatic artery ligation and placement of intra-arterial catheters for infusion chemotherapy directed at primary or metastatic liver tumors was undertaken to assess the magnitude of the problem, produce future earlier recognition of the complication, and assess the adequacy of abscess management. In five of the six affected patients, the common hepatic artery was ligated just proximal to the gastroduodenal artery, which was used for the retrograde placement of the infusion catheter into the hepatic artery. In one patient in whom the left and right hepatic arteries had separate points of origin, each vessel was cannulated and ligated. The symptoms of fever, pain, and prostration are similar to those reported for hepatic abscesses of other etiologies. Laboratory confirmation of leukocytosis and impaired hepatic function may be obscured by myelosuppressive chemotherapeutic agents and an already severely damaged liver. Abnormal gas patterns in the area of the liver developed in all the patients and were often confirmed by ultrasound or by computed axial tomography. Both the reduced hepatic blood supply and the development of large amounts of nonviable tumor (the goal of the procedure) that act as a nidus for bacterial colonization predispose to the development of abscesses in these patients. It appears that cryptogenic abscesses with obscure etiologies arise from secondarily infected hepatic infarcts seeded by colon organisms via the portal vein. Antibiotic therapy alone is rarely effective, simple aspiration is not sufficient, and less-than-adequate surgical exploration results in multiple procedures. Treatment should always be surgical debridement and drainage. Abscesses tended to develop later than expected, usually after antibiotic prophylaxis was withdrawn, implying a causal relationship. Four of the six patients died (average survival from ligation, 348 days), and two are alive 378 and 102 days, resp., since ligation. These figures compare well with the average survival of 337 days from ligation among the 45/57 patients who died without developing abscesses and the 12/57 without abscesses who remain alive an average of 2 yr.

7787 INTRAHEPATIC PIGMENT AND CRYSTAL FORMS IN PATIENTS WITH CEREBROTENDINOUS XANTHOMATOSIS (CTX).

(Eng.) Salen, G.; Zaki, G.; Sabesin, S.; Boehme, D.; Shefer, S.; Mosbach, E. H. (East Orange Veterans Admin. Hosp., Tremont Ave., East Orange, NJ 07019). *Gastroenterology* 74(1):82-89; 1978.

Unique electron-dense bodies and crystal forms detected in the liver cells of two patients with cerebrotendinous xanthomatosis (CTX) are described. Histologic examination of plastic-embedded sections stained with toluidine blue demonstrated the presence of excessive dark pigment granules in the hepatocytes. Ultrastructural examination showed that this pigment was distributed widely throughout the hepatocytes and Kupffer cells and was in two forms. Amorphous electron-dense material was seen enveloped by the smooth endoplasmic reticulum or was found free-floating in the cytosol. Crystals were also found in the cytosol and resembled rhomboid-shaped bodies. The pigment resembles lipofuscin, especially in its osmiophilic stainability; yet because of its profuse and excessive deposition within the liver cells, it may be related to the basic biochemical defect in bile acid synthesis in CTX. The authors propose that the accumulation of such material may indicate the presence of nonmetabolizable bile alcohols resulting from a defect in bile acid synthesis.

7788 TRYPTOPHAN AND HEPATIC COMA. (Eng.)

Ono, J.; Hutson, D. G.; Dombro, R. S.; Levi, J. U.; Livingstone, A.; Zeppa, R. (Sch. Medicine, 1208-1 Usuki-Cho, Kagoshima City, 890, Kagoshima, Japan). *Gastroenterology* 74(2, Part 1):196-200; 1978.

To clarify the involvement of tryptophan (Trp) in the pathogenesis of hepatic coma, an investigation was carried out to elucidate the plasma factors responsible for the increased levels of Trp found in the cerebrospinal fluid (CSF) of patients in hepatic coma. Factors believed to be involved in the transport of Trp into the central nervous system were measured in 10 patients with liver cirrhosis and in stage III or IV hepatic coma, 10 patients with stable cirrhosis, and 10 healthy contr
Neither plasma total nor free Trp levels were sign
cantly altered in cirrhotic patients compared with controls, but in hepatic coma patients, the plasma free Trp level was significantly elevated (1.94 ±
µmol/dl) and the plasma total Trp level decreased
± 0.3 µmol/dl) compared with control levels (0.43
0.03 and 4.7 ± 0.5 µmol/dl, resp., $p<0.001$ and $p<0$
resp.). The CSF levels of Trp were significantly greater than normal in both patient groups ($p<0.00$
but were more elevated in the coma patients than i
the cirrhotics ($p<0.05$). Plasma free fatty acid levels were significantly elevated in both cirrhotics ($p<0.05$) and in hepatic coma patients ($p<0.001$) compared with controls, but were more elevated in the coma patients than in the cirrhotics ($p<0.001$). Serum albumin concentrations were significantly decreased in cirrhotics ($p<0.02$
but more significantly decreased in hepatic coma patients ($p<0.001$). The serum total bilirubin level was moderately elevated in cirrhotics (1.0-1.9 mg/dl) compared with controls (0.41-0.94 mg/dl
but markedly elevated in hepatic coma patients (1.5-67 mg/dl). Plasma branched chain amino acid (BCAA) levels were significantly lower than normal in both cirrhotics and hepatic coma patients ($p<0.$
$p<0.05$); isoleucine and leucine levels were also s
nificantly lower in the hepatic coma patients than
the cirrhotics ($p<0.01$ and $p<0.05$, resp.). No sig
ficant differences were found in the concentration
CSF BCAA in any of the groups compared. Among the aromatic amino acids, plasma phenylalanine, tyrosine (Tyr), and methionine (Met) were significantl
increased in hepatic coma patients ($p<0.01$, $p<0.00$
and $p<0.001$, resp.), but only Tyr and Met were significantly increased in cirrhosis without coma ($p<0.01$ and $p<0.001$, resp.). The CSF levels of these three amino acids were significantly higher in both patient groups ($p<0.001$-$p<0.05$), but no significant differences between the two groups were observed. The data demonstrate that, whereas the elevated CSF Trp levels in cirrhotics versus controls may be attributable to decreased plasma BCAA levels, the elevated CSF Trp levels in hepatic coma patients compared with stable cirrhotic patients may be attributable to increased plasma free Trp concentrations.

7789 SYMPTOMATIC NONPARASITIC LIVER CYSTS.

(Eng.) Hadad, A. R.; Westbrook, K. C.; Graham, G. G.; Morris, W. D.; Campbell, G. S. (Univ
Arkansas for Medical Sciences, 4301 W. Markham, Little Rock, AR 72201). *Am. J. Surg.* 134:739-744; 1977.

The cases of four women with symptomatic nonparasitic liver cysts are presented. The patients ranged in age from 49 to 80 yr. All presented with

bdominal mass. Radiologic studies demonstrated
lacement of the intraabdominal viscera by ex-
sic pressure in all cases, and a ^{99m}Tc liver
revealed filling defects in three patients.
ultrasound examination performed in three cases
ested a cystic mass, although the mass was ini-
ly thought to be a pancreatic pseudocyst before
ation in one patient. Surgical exploration re-
ed multiple cysts in three cases and a solitary
in the fourth. The largest cysts were mar-
alized, and the smaller ones were drained. Mi-
copic section of the cyst walls revealed fi-
s tissue, hepatocytes, aberrant bile ducts, and
ning of cuboidal and columnar cells. The re-
s in these patients and in others reported in
literature suggest that the diagnosis of liver
s can be established with routine and special
ologic studies; that laparotomy is indicated
patients with symptoms or uncertain diagnosis;
surgical management should be guided by cyst
, location, and content; and that definitive
ical treatment is indicated only for cysts
er than 10 cm.

CONGENITAL CYSTIC DILATATION OF THE INTRA-HEPATIC BILE DUCTS (CAROLI'S DISEASE).

.) In der Maur, G. A. P.; Zuidema, B. J. J.;
sma, S. A.; Blom, W. F. (Dept. Diagnostic Radi-
y, St. Geertruiden Ziekenhuis, Fesevurstraat
eventer, Netherlands). *Radiol. Clin.* 47(3):
189; 1978.

clinical features of Caroli's disease (seg-
ally dilatated intrahepatic bile ducts) are
ribed with reference to an affected 32-yr-old
n. The principal characteristics of the dis-
are segmental saccular or cystic dilatations
he intrahepatic bile ducts; predisposition to
iasis, cholangitis, and liver abscesses; and
of involvement of the other bile ducts and
bsence of liver cirrhosis and portal hyper-
ion. The symptoms consist primarily of some-
s colicky pain in the right upper quadrant, and
disease is generally diagnosed on the basis of a
perative cholangiogram. When Caroli's disease is
ected, echography can be a valuable diagnostic
. The disease is usually diagnosed in men and
n between 30 and 40 yr of age and is generally re-
ed as a grave condition because of its tendency
ead to serious complications (e.g., liver ab-
s, cholangitis, and sepsis). Its pathogenesis
bscure, but it is suspected that an embryonic
lopmental disorder in the wall of the bile ducts
es cysts via physiological periodic increases
ressure.

UPTAKE OF ^{99m}Tc-PYROPHOSPHATE IN LIVER NECROSIS.

(Eng.) Echevarria, R. A.;
nno, C.; Davis, D. K. (St. Petersburg General
, St. Petersburg, FL 33710). *Clin. Nucl. Med.*
:322-323; 1977.

case of a patient in whom the liver was visu-
ed on a routine bone scan performed with ^{99m}Tc-
phosphate is presented. The patient was a 77-yr-old diabetic man hospitalized for congestive heart failure. The bone scan was performed because the patient underwent resection of a rectal adenocarcinoma 2 yr previously. No skeletal metastases were demonstrable, but there was marked uptake of the radionuclide by the liver with an irregular central cold area. Forty-eight hours later, a ^{99m}Tc-sulfur colloid scan of the liver showed a similar liver image with a central defect of uptake and compensatory uptake of colloid by the vertebral and rib bone marrow. The patient died a week later, and at autopsy the liver showed a gross "nutmeg" appearance. There was a metastatic mass corresponding to the cold area of the scans. A few smaller metastases that had not been visualized were present. Severe centrilobular hemorrhagic necrosis was observed. The radionuclide is thought to have been taken up by the necrotic liver cells. The possibility that the necrotic liver may be consistently visualized by bone-seeking radionuclides deserves further exploration.

7792 HEPATIC TUMORS: POSSIBLE RELATIONSHIP TO USE OF ORAL CONTRACEPTIVES.

(Eng.)
Klatskin, G. (Dept. Medicine, Yale Univ., 333
Cedar St., New Haven, CT 06510). *Kurume Med. J.*
24(Suppl.):S1-S26; 1977.

The potential role of oral contraceptives in the pathogenesis of hepatic tumors was investigated in a survey of 105 cases reported in the literature since 1972, including 10 cases of malignant tumors and 95 cases of benign tumors (69 hepatic cell adenomas [HCA] and 26 cases of focal nodular hyperplasia [FNH]). While 53% of the patients had used oral contraceptives for more than 5 yr, 11% had used them for less than 1 yr. The estrogen in the contraceptive was mestranol in 87% of the cases and ethinyl estradiol in 13%. Except for the absence of cirrhosis, the clinical features of patients with malignant hepatic tumors associated with the use of oral contraceptives were similar to those that usually accompany such tumors. The benign tumors produced a wide variety of symptoms and many of the clinical and morphological features were significantly different in users of oral contraceptives compared with nonusers (138 cases of HCA; 234 cases of FNH). The presenting complaints, tumor size, and appearance for both HCA and FNH in contraceptive users and nonusers are summarized in detail. Functional, scintiscan, and arteriographic findings and the clinical course of the disease in contraceptive users are tabulated and discussed. A high survival rate (92%), remarkable tolerance to surgery, and a decrease in tumor size after discontinuation of oral contraceptive use were noted. The morphology of the tumors in contraceptive users is discussed at length and the possibility is suggested that the two types of tumors may be related in some cases. Evidence supporting a hormonal role in the pathogenesis of hepatic tumors and evidence suggesting that vascular changes in hepatic tumors reflect hormonal effects is presented. These facts may indicate that oral contraceptive use merely enhances the growth rate of small, otherwise unrecognized tumors. It is concluded that evidence implicating oral contraceptives in the pathogenesis of hepatic tumors is as yet circumstantial.

7793 HEPATOCELLULAR CARCINOMA AND HEPATITIS B.

(Eng.) Zuckerman, A. J. (London Sch. Hygiene Tropical Medicine, London WC1E 7HT, England). *Trans. R. Soc. Trop. Med. Hyg.* 71(6):459-461; 1977.

The relationship between hepatitis B (HB) and the pathogenesis of cirrhosis and primary hepatocellular carcinoma is reviewed briefly. The availability of specific laboratory tests for HB infection has demonstrated an excess prevalence of markers of active HB virus (HBV) infection in patients with primary liver cancer when compared with the general population; those markers are HB surface antigen (HBsAg) and its homologous antibody, HB core antigen (HBcAg) and its homologous antibody, and HBeAg. The cause and effect relationship is not clear: does the infectious agent drive the processes of macronodular cirrhosis and carcinoma or do these latter disease states predispose to greater susceptibility to HBV infection and the development of the carrier state? An early age of HBV infection such that the carrier state occurs most frequently in infants and children appears to be an important etiological factor in cirrhosis and carcinoma; it seems likely that persistent HBV infection occurs before the onset of chronic liver damage. Some progress is being made in demonstrating that HBV infection precedes the development of cancer, that tumor cells contain virus-specific molecules or antigens, that cancer cells can produce the virus, and that the virus can transform cells in culture or induce hepatocellular carcinomas in experimental animals. Much more work is required to elucidate the contributions of genetic, immunological, nutritional, and hormonal factors; mycotoxins; chemical carcinogens; other environmental factors; and HBV to hepatocellular carcinogenesis.

7794 HEPATOADENOMA AND FOCAL NODULAR HYPERPLASIA: PITFALLS IN RADIOCOLLOID IMAGING.

(Eng.) Salvo, A. F.; Schiller, A.; Athanasoulis, C.; Galdabini, J.; McKusick, K. A. (Maine Medical Center, Portland, ME 04102). *Radiology* 125(2):451-455; 1977.

The cases of three patients with hepatoadenoma or focal nodular hyperplasia in whom radiocolloid imaging was used in the diagnosis are presented. The patients were women, ranging in age from 39 to 45 yr, and two had been taking oral contraceptives. The first patient was asymptomatic, but had a right upper quadrant abdominal mass, which was palpable on routine examination. A ^{99m}Tc-sulfur colloid liver scan demonstrated that the inferior margin of the right lobe of the liver, in a position corresponding to that of the mass, was indented. At laparotomy, the tumor was found to be a well-demarcated but nonencapsulated smooth round mass composed of cords of uniform cells closely resembling normal hepatocytes. The cells were arranged in irregular trabeculae from one to five cells thick and were separated by sinusoids lined by endothelium and Kupffer cells. No portal tracts or bile ducts were present; tumor cell trabeculae around irregularly spaced venous channels occasionally were surrounded by areas of fibrosis. The second patient's only symptom was hepatomegaly, discovered at routine physical examination. Abdominal angiography revealed a massively enlarged right lobe with a hypervascular mass. The ^{99m}Tc-sulfur colloid scan showed irregularly shaped areas of decreased activity involving half the right lobe and a portion of the left lobe. At surgery, an attempt was made to remove a large vascular tumor in the lower half of the right lobe, but dissection revealed extension into the left lobe. Needle biopsy confirmed the diagnosis of hepatoadenoma. Extensions of the tumor were found, with multiple projections into normal liver across the surgical planes of dissection. Copious bleeding from the resection margin could not be controlled, and the patient died during surgery. At autopsy, the tumor was found to be similar to that in the first patient, except for a slightly lo ulated contour, a more pronounced increase in tumor cell glycogen content, and the presence of many randomly scattered necrotic foci. A liver mass was discovered in the third patient at hysterectomy. Postoperatively, a liver scan demonstrated a normal liver except for a slight increase in radioactivity in the central portion. At laparotomy, a diagnosis of focal nodular hyperplasia was made.

7795 CURRENT TREATMENT OF PRIMARY MALIGNANT HEPATOBLASTOMA IN CHILDHOOD (A SURVEY IN AUSTRIA).

(Ger.) Sauer, H.; Kurz, R.; Haas, H.; Mutz, I. (Kinderchirurgie, Universitat Graz, Heinrichstrasse 31, A-8010 Graz, Austria). *Z. Kinderchir.* 22(3):313-323; 1977.

The diagnosis and treatment of hepatoblastoma in 11 children are described. The patients included 6 boys and 5 girls aged 5 days to 15 yr; two-thirds of the patients were under 2 yr. Palpable liver tumor was the common symptom and anemia was found i five cases, but the other laboratory findings were unremarkable. The tumors were diagnosed by angiography, liver scanning, and sonography. The alpha-1-fetoprotein level was abnormally high in five of s ven investigated cases. The tumor was localized to the right lobe in five cases, to the left lobe in f and to both lobes in two. Embryonic hepatoblastoma was diagnosed in 10 cases and hepatocellular carcin in 1. Nine patients were in clinical stage II, and two were in stage III. Radical surgery was performed in 10 patients; it consisted of lobectomy or extended lobectomy in 9 and of segment resection in 1. Exploratory laparotomy was performed in two inoperable patients with bilateral involvement. Three patients also received postoperative radiotherapy. Six patients, including one irradiate patient, received postoperative chemotherapy wi cyclophosphamide (CP) or vincristine (VCR, one case each), with the combination of VCR, CP, and actinomycin D (AD), with VCR + CP + adriamycin + 5-fluorouracil (5-FU) or with VCR + CP + 5-FU.

ee patients developed metastases; two
recurrences. Three patients died after 8 months
5 yr; the others have been alive for 1 week to
yr (one of them has been alive with metastases
9 months).

6 INTRAHEPATIC HEMATOMA RESULTING IN OB-
STRUCTIVE JAUNDICE: AN UNUSUAL COMPLI-
ION OF LIVER BIOPSY. (Eng.) Chiprut, R. O.;
enwald, R. A.; Morris, S. J.; Zeppa, R.; Schiff,
R. (Veterans Admin. Hosp., 1201 N.W. 16th St.,
mi, FL 33125). *Gastroenterology* 74(1):124-127;
8.

case of a patient who developed obstructive
ndice as a complication of a liver biopsy is
sented. The patient, a 17-yr-old girl, under-
t the liver biopsy after a diagnosis of acute
e B viral hepatitis was made. The biopsy was
formed using the Menghini technique. The pa-
nt developed pain at the biopsy site and did
adhere to absolute bed rest. The patient ex-
ienced epigastric discomfort for 10 days after
procedure and then noted recurrence of ano-
ia and jaundice. She was readmitted 22 days
er the biopsy with a presumed diagnosis of re-
rent hepatitis. A ^{99m}Tc-sulfur-colloid liver
n revealed a large filling defect, and ultra-
ography of the liver was compatible with a di-
ed biliary tree without visualization of a
initive mass. A "skinny" needle percutaneous
nshepatic cholangiogram demonstrated a dilated
ht hepatic duct system with apparent blockage
the level of the bifurcation. The left hepatic
iary system was incompletely visualized. The
er enzymes and bilirubin level were elevated at
s time. Twenty-four hours after beginning par-
eral hydrocortisone therapy (for an allergic
ction to iodinated contrast material during an
empt to perform a hepatic arteriogram), the
um bilirubin level began to decrease. Six days
er, a rose bengal scan showed normal excre-
n of the material into the duodenum, and a re-
t ^{99m}Tc scan showed resolution of the defect.
patient was asymptomatic, although remaining
atitis B surface antigen-positive, at a follow-

likely that an expansion of an intrahepatic
atoma caused compression of the biliary tree.
onset of pain at the biopsy site followed by
gastric pain are highly suggestive of the de-

er biopsy.

7 LIVER FINDINGS IN SJOGREN'S SYNDROME.
(Ger.) Rau, R. (Stadtspital Triemli,
mensdorferstrasse 497, 8063 Zurich, Switzerland).
xis 66(45):1437-1441; 1977.

dies on the hepatic involvement of the liver in
gren's syndrome (SS) are reviewed. Hepatomegaly
been reported in 10-20% of the patients with
Increased alkaline phosphatase activity was
nd in about 25%, increased amino transferase ac-
ities in 10-20%, and pathological BSP test in
50% of the patients. These changes are indicative of an impaired liver function. Abnormal thymol and cephalin flocculation tests are due to hypergammaglobulinemia, which is very common in SS. Antibodies to mitochondria and smooth muscles are markedly more frequent (8-12%) in SS than in rheumatoid arthritis or seronegative arthropathies. Liver biopsy specimens show lymphocyte and, rarely, plasma cell infiltration of the portal fields. Primary biliary cirrhosis and chronic active hepatitis are more frequent in SS than in the general population. Conversely, symptoms of SS were found in about 40% of the patients with chronic active hepatitis, and in 70-100% of the patients with primary biliary cirrhosis. The findings indicate that autoimmune liver disease is a systemic manifestation of SS.

7798 HEPATIC ANGIOGRAPHY IN HEREDITARY HEMORRHAGIC TELANGIECTASIA. (Eng.) James, P.; Delany, D. (Dept. Radiology, Univ. North Carolina, Chapel Hill, NC 27514). *Gastrointest. Radiol.* 2(2):149-152; 1977.

The cases of three patients with gastrointestinal bleeding and characteristic radiologic findings of hereditary hemorrhagic telangiectasia are presented. The first two patients, a woman and her mother, developed symptoms at 41 and 49 yr of age, resp.; the third patient was a 58-yr-old man. The first patient underwent an upper gastrointestinal examination shortly before presentation that showed normal results. However, a chest x-ray demonstrated mild cardiomegaly and generalized pulmonary vascular prominence, and celiac and superior mesenteric angiography demonstrated diffuse arteriovenous shunting throughout the liver. Endoscopy revealed gastric mucosal telangiectasia, although a biopsy was reported to be normal. Visceral angiography in the first patient's mother demonstrated diffuse hepatic arteriovenous fistulas and an angioma of the right colon. Histologic features of the liver included minimal portal fibrosis and prominent subcapsular vascular spaces, but it was otherwise normal. Visceral angiography was prompted in the third patient by the presence of a loud systolic bruit in the epigastrium. Celiac and renal artery stenosis in addition to massive generalized hepatic arteriovenous fistulization were demonstrated. The liver biopsy was normal. These cases demonstrate that the chest radiograph may show a chronic mild hyperdynamic state in hemorrhagic telangiectasia and that the liver biopsy results may be unremarkable in contrast to the angiographic results.

LIVER AND BILIARY TRACT

Hyperbilirubinemic States

) THE BRONZE BABY SYNDROME: A COMPLICATION OF PHOTOTHERAPY. (Ger.) Radermacher,
.; Noirfaise, A.; Hornchen, H.; Maier, R. D.;
lke, K. H. (Abteilung Kinderheilkunde, RWTH,
hestr. 27-29, 5100 Aachen, W. Germany). *Klin.*
iatr. 189(5):379-384; 1977.

emature twin baby (birth weight 800 g) with
ncreased bilirubin level (3.5 mg/100 cm^3) and
out kernicterus underwent phototherapy (3,700
150 W, wavelength 390-490 nm) beginning
diately after birth. The total serum bilirubin
l rose to 10.5 mg/100 cm^3 on the 6th day of
during the treatment, and dropped to 8.5 mg/
cm^3 on the 8th day. This increase was ac-
anied by an intense greyish-brown discoloration
he skin, serum, urine, peritoneum, spleen,
r, urinary bladder, pericardium, and visceral
ra. An increased coproporphyrin level was
d in the serum. The patient died from hyalini-
on of the lungs, kidney failure, and consumption
ulopathy on the 11th day of life. The bili-
n breakdown products, present in high concen-
ion, may exert neurotoxic effects, because
are not eliminated adequately by the normal
ary tract in bronze baby syndrome.

THE DUBIN-JOHNSON SYNDROME. (Fre.) Van de Velde, J. M.; Parent, M. (Notre-Dame
., P.O. Box 1560, Station C, Montreal, Canada).
n *Med. Can.* 106(12):1630-1634; 1977.

cases of the Dubin-Johnson syndrome are reported
atients aged 9, 15, 45, 50, and 56 yr. The syndrome can be differentiated from Gilbert's disease by the presence of conjugated bilirubin in the urine, hepatic pigmentation, and abnormal retention of BSP. The Dubin-Johnson syndrome must also be differentiated from the Rotor syndrome, which appears to be an attenuated form of the disease. Often, patients in the same families have one or the other of these latter two syndromes. Transmission of the Dubin-Johnson syndrome is probably by an autosomal dominant allele with feeble penetration. Prognosis is excellent, and only phenobarbital is recommended as treatment.

7822 HEPATIC JAUNDICE OF HEREDITARY ORIGIN. (Por.) de Magalhaes, A. F. N. (Ciencias Medicas da Universidade Estadual de Campinas, Sao Paulo, Brazil). *Arq. Gastroenterol.* 14(4):215-223; 1977.

LIVER AND BILIARY TRACT

Nonviral Hepatitis and Hepatic Injury

7823 ALLOPURINOL HEPATOTOXICITY: CASE REPORT AND LITERATURE REVIEW. (Eng.) Chawla, S. K.; Patel, H. D.; Parrino, G. R.; Soterakis, J.; LoPresti, P. A.; D'Angelo, W. A. (Queens Hosp. Center, 84-69 164th St., Jamaica, NY 11432). *Arthritis Rheum.* 20(8):1546-1549; 1977.

A case of allopurinol hepatotoxicity is reported, and the literature concerning this complication is reviewed. The patient was a 44-yr-old man with gouty arthritis who had been receiving 300 mg of allopurinol daily for 1 week prior to admission. At this time, he had a 3-day history of diplopia, left upper quadrant fullness, and pain. Hepatosplenomegaly was present, and the SGOT, alkaline phosphatase, and total bilirubin levels were 50 mU/ml, 98 mU/ml, and 1.8 mg%, resp. Liver biopsy revealed fatty changes, focal necrosis, and noncaseating granulomata with scattered eosinophils. The patient's symptoms improved promptly after allopurinol was discontinued, and the hepatosplenomegaly disappeared after 4 weeks. Six cases of allopurinol-induced hepatotoxicity have been reported, and the present case is the third with allopurinol-induced granulomatous hepatitis.

7824 HEPATITIS DUE TO HALOGENATED ANESTHETICS. (Fre.) Duheille, J. (Faculte A de Medecine de Nancy-Brabois, Boite postale n° 1080, 54019 Nancy Cedex, France). *Ann. Anesthesiol. Fr.* 17(3): 339-345; 1976.

The incidence of hepatitis following anesthesia with halothane is about 1 in 35,000. It can occur at any age, but the patient over 45 yr old is somewhat more susceptible, and the postmenopausal woman is a most likely candidate. Repeated exposure to halothane anesthesia has been incriminated etiologically, but hepatitis does occur after a single exposure. The hepatitis signs (fever, chills, rash, icterus) may appear within 4-17 days after anesthesia. The hepatitis can resolve spontaneously or progress to a fatal outcome. Biopsy or autopsy studies of the liver show pathology ranging from simple cholestasis to that resembling viral hepatitis or chronic active hepatitis. The mechanisms of hepatitis induced by halothane are discussed from the aspect of determining the susceptible patient prior to operation. Autoimmunization to liver components appears to be the most likely mechanism. Routine immunological testing, particularly for the antinuclear antibody with the Dane particle, although technically rather difficult, may serve to identify susceptible patients.

7825 ELEVATION OF SERUM XANTHINE OXIDASE ACTIVITY FOLLOWING HALOTHANE ANESTHESIA IN MAN. (Eng.) Giler, S.; Eshel, Y.; Pinkhas, J.; Ventura, E.; Levy, E.; Urca, I.; *et al.* (Tel-Aviv Univ. Medical Sch., Beilinson Medical Center, Petah-Tikva, Israel). *Experientia* 33(10):1356-1358; 1977.

The specific and highly sensitive marker for acut liver damage, serum xanthine oxidase (SXO), was used to clarify whether halothane or methoxyfluor is hepatotoxic in man. Of 60 patients without liver disease who were undergoing elective surger 31 received halothane (1.0%), 12 received methoxyfluorane (1.0% for 5 min, then 0.5% for remainder of operation), and 17 patients served as controls In controls (who received Fentanyl, 0.002 mg/kg and Alloferine, 0.2 mg/kg, i.v.), the mean SXO, l tate dehydrogenase (LDH), and SGOT values followi anesthesia were not significantly elevated, in co parison with the preoperative values. In the hal thane group, in comparison with the preoperative values, there was a significant elevation in SXO tivity immediately following completion of anesthesia, the activity increasing to maximum value on the 3rd postoperative day (>sixfold the preoperative value), and then decreasing gradually. SXO level was still significantly elevated on the 7th postoperative day, the last day it was measured. When the SXO levels on the different days following halothane anesthesia were compared with the respective values obtained in the contro group, a significant elevation was found immediately following anesthesia and on the 1st and 3rd postoperative days only. The post-halothane LDH and SGOT levels, which rose significantly whe compared with their respective preoperative value the former on the first ($p<0.01$), third ($p<0.001$ and fifth ($p<0.01$), the latter on the first (p<0. and third ($p<0.01$) postoperative days, did not differ significantly from the respective values following control anesthesia. The mean SXO level in the methoxyfluorane-treated patients was significantly elevated above the preoperative level only on the first postoperative day (almost fourf but when compared with the respective values following control anesthesia, no significant elevation was found at any time. LDH and SGOT levels were also not altered. These results suggest tha halothane, but not methoxyflurane, causes specifi hepatocellular damage.

7826 ENTERIC FEVER: A CLINICOPATHOLOGIC STU OF 104 CASES. (Eng.) Nasrallah, S. M. Nassar, V. H. (Emory Univ. Sch. Medicine, 69 Butl St., S.E., Atlanta, GA 30303). *Am. J. Gastroenter ol.* 69(1):63-69; 1978.

A clinicopathologic study of 104 cases of culture proven enteric fever was conducted to review the systemic manifestations and complications of the disease and to emphasize the frequency and signifi cance of liver involvement. One fatal case with disseminated intravascular coagulation is describ in detail. Clinical findings included fever (100 of cases), bradycardia (75%), splenomegaly (43%), hepatomegaly (33%), and rose spots (9%). The pri

al complications were anemia (64% of those test-
, typhoid hepatitis (30%, judged by combined
lirubin, SGOT, and SGPT values), relapse (12%),
l bleeding (occult, 12%; gross, 6%). The mean
lues of the abnormal liver tests included a total
lirubin of 8.1 mg%, an SGOT of 82 ImU, and an
T of 86 ImU. Liver enlargement occurred in one-
rd of the patients; however, 55% of all cases
h abnormal elevations of SGOT and/or SGPT showed
liver enlargement. Abnormal liver tests in four
seven patients with relapse indicate a rela-
nship between relapse and typhoid hepatitis.
these patients, the Kupffer cells were enlarged
hyperplastic. In all cases, pathology con-
ted of typhoid nodules of variable size and fre-
ncy depending on the severity of the condition.
fatal outcome of a rare complication of enteric
er, consumptive coagulopathy, is reported; early
ognition of this rare occurrence is vital. Most
the complications were reversible following
ibiotic therapy with chloramphenicol (the drug
choice) or Co-Trimoxazole.

LIVER AND BILIARY TRACT

Acute Viral Hepatitis

) ON THE LATE PROGNOSIS OF TYPE A VIRUS
HEPATITIS. (Eng.) Weigl, E.; Bach, H.
sp. Eisenhuttenstadt, DDR--122 Eisenhuttenstadt,
ermany). *Acta Hepatogastroenterol. (Stuttg.)*
):355-356; 1977.

prognosis of type A viral hepatitis was studied
,283 cases that occurred in one East German
between 1960 and 1970. Pathological sequelae
he acute disease developed in 8.2% of all these
s. Seventy-nine patients developed chronic
istent hepatitis, and five others developed
nic aggressive hepatitis. Acute viral hepatitis
ressed directly to cirrhosis in 6 patients, and
hol worsened the course of the disease in 10
ents. At the end of the observation period,
atients still showed pathological sequelae, and
e dead.

HB-Ab IN SWEAT. (Eng.) Telatar, H.;
Kayhan, B.; Kes, S.; Karacadag, S. (Gaz-
anposa, Hereke Sokak No. 4, Ankara, Turkey).
J. Gastroenterol. 68(5):492-493; 1977.

sweat of 10 patients with hepatitis B surface antigen (HBsAg)-positive liver cirrhosis and 20 patients with HBsAg-positive viral hepatitis was examined by radioimmunoassay for the presence of HBsAg. The sweat (1.5 ml) was collected, dried, and dissolved in 0.2 ml of buffer solution. The sweat from all patients was found to be HBsAg-positive. This study indicates that direct contact is one of the most important factors in the epidemiology of this disease and may be even more important in asymptomatic carriers.

7832 SIMULTANEOUS PRESENCE IN SERUM OF HBsAg AND ANTI-HBs OF DIFFERENT SPECIFICITIES. (Eng.) Moraczewska, Z.; Madalinski, K.; Holland, P. V. (Inst. Hematology, Warsaw, Poland). *Intervirology* 9(3):189-192; 1978.

The case of a patient in whom hepatitis B surface antigen (HBsAg) and antibodies to HBsAg (anti-HB) of different specificities were found in the serum during his third attack of acute viral hepatitis is presented. The patient had attacks of hepatitis 29 and 67 days apart. The presence of HBsAg was established by complement fixation and was found to be subtype *ayw*. The serum was checked against a panel of HBs antigens of *adw* and *ayw* subtypes. Precipitation reactions were obtained with all 12 HBsAg sera of subtype *adw* but not with any of the 8 HBsAg/*ayw* sera employed. Absorption of anti-HBs present in the serum sample, presumably monospecific anti-*d* antibody, was attempted. The patient's serum was absorbed with HBsAg/*adw*- or HBsAg/*ayw*-containing serum, and the results were compared to absorption with HBsAg-negative serum. Only the HBsAg/*adw* serum absorbed the anti-HBs from the sample. The patient's serum reacted only with HBs antigens that contained the *d* determinant, thus confirming it was a monospecific anti-*d* antibody. Electron microscopy showed no evidence of circulating immune complexes in the precipitate after centrifuging. These results indicate that both HBsAg of *ayw* specificity and monospecific anti-HBs/*d* antibody were present. This condition probably results from two infections with hepatitis B viruses of different subtypes--first *adw* and then *ayw*.

7833 NON-A NON-B HEPATITIS. (Eng.) Anonymous. (No affiliation given). *Br. Med. J.* 1(6118):942-944; 1978.

Current information on non-A non-B hepatitis is briefly reviewed. Studies on post-transfusion cases have shown that the mean incubation period is similar to that of hepatitis B, although it ranges from 18 to over 100 days. The clinical course is also similar to hepatitis B, but the symptoms, jaundice, and peak bilirubin and transaminase levels are more short-lived. The disease is thought to be spread by both parenteral and nonparenteral routes. The results of an inoculation study in which blood from asymptomatic blood donors implicated in transmitting post-transfusion hepatitis was inoculated into volunteers suggest that there exists a transmissible agent and a chronic carrier state in non-A non-B hepatitis, and this has been substantiated by studies in chimpanzees, in which there has been evidence of successful transmission. Two studies have shown that gammaglobulin is useful in preventing non-A non-B hepatitis. These studies also showed that 60-90% of post-transfusion hepatitis in the United States is currently non-A non-B and that it is transmitted mostly through commercial blood donations. An important obstacle to diagnosing non-A non-B hepatitis is the lack of a commercial kit for the diagnosis of hepatitis A antigen. A more direct method for the characterization of non-A non-B agent(s) by a serological test may soon be possible.

Chronic Hepatitis

SERUM SOMATOMEDIN PEPTIDES MEASURED BY
SOMATOMEDIN A RADIORECEPTOR ASSAY IN CHRON-
VER DISEASE. (Eng.) Takano, K.; Hizuka, N.;
me, K.; Hayashi, N.; Motoike, Y.; Obata, H.
o Women's Medical Coll., Tokyo 162, Japan).
in. Endocrinol. Metab. 45(4):828-832; 1977.

somatomedin levels were determined, using a
omedin A radioreceptor assay, in 25 patients
liver cirrhosis, 28 patients with chronic
itis, and 131 healthy subjects. The levels
rmal subjects ranged from a mean of 1.00 ±
J/ml in those aged 20-29 yr to 0.80 ± 0.26
in those aged 60-86 yr. The mean level in the
otic patients (0.47 ± 0.05 U/ml) and that in
atients with chronic hepatitis (0.60 ± 0.04 U/
ere significantly lower than that in the normal
ols ($p<0.005$). The levels of somatomedin A
e patients with liver cirrhosis were lower
those in the patients with chronic hepatitis
<$p<0.1$). In the cirrhotic patients and the
nts with chronic hepatitis, there were posi-
correlations between the somatomedin level
ne (a) albumin level ($r=0.53$, $p<0.005$), (b)
nesterase level ($r=0.53$, $p<0.005$), (c) total
sterol level ($r=0.70$, $p<0.01$), and (d) thrombo-
($r=0.61$, $p<0.05$). There was a negative cor-
ion between somatomedin A and the indocyanine
retention test ($r=-0.50$, $p<0.05$). These re-
confirm earlier results obtained with bio-

ght microscopic and electron microscopic
gs in liver biopsy specimens from a woman
ceived immunosuppressive therapy with corti-
oids and Imuran for chronic active hepatitis
esented. Round cell infiltration of the
connective tissue was seen. The inflamma-
nd necrotic changes were less marked than
the Imuran treatment. Isolated or clustered
haped formations with a diameter of 20-25 nm
) were found in the nucleus of nearly all
lial cells examined. Most of these particles
were localized near the nuclear membrane, sometimes in the pars amorpha. These particles were found to consist of osmiophilic granules 2-3 nm in diameter. Core particles were found only occasionally in the cytoplasm. Electron-dense filaments of varying length, and with a diameter of about 23 nm (surface antigen, coat) were found in the canaliculi of the smooth endoplasmic reticulum of the ground glass hepatocytes. Dane particles were not seen at all. Isolated spherical or ring-shaped virus-like particles with a diameter of 80 nm were found in some cells, mainly in the hyaloplasm; they may be due to a second virus infection. The immunosuppressive treatment is assumed to have played a certain role in the appearance of B virus components, because they were absent in the biopsy specimens taken before the immunosuppressive treatment.

LIVER AND BILIARY TRACT

Alcoholic Liver Disease

HISTOLOGICAL AND BIOCHEMICAL INDICES OF
PROGRESSIVE LIVER INJURY IN PATIENTS WITH
LIC FATTY LIVER. (Eng.) Van Waes, L.; Demeulenaere, L.; Lieber, C. S. (Bronx Veterans Admin. Hosp., Bronx, NY). *Acta Gastroenterol. Belg.* 40(7/8):271-277; 1977.

Histological and biochemical abnormalities that may be indices of progressive liver injury in patients with alcoholic fatty liver are reviewed. In long-term follow-up studies, 38-58% of patients who developed alcoholic hepatitis before the presence of fibrosis or cirrhosis rapidly progressed to cirrhosis. Studies in the baboon indicate that pericentral sclerosis in the absence of manifest alcoholic hepatitis is also a precursor lesion of cirrhosis. In some baboons, chronic alcohol feeding induced central sclerosis beginning at the fatty liver stage and invariably progressing to fibrosis or cirrhosis. Animals that did not develop the lesion did not progress beyond fatty liver. The fate of the lesion upon abstinence from alcohol remains to be documented. The use of blood transaminase levels as a biological marker of alcohol-induced liver disease is not satisfactory because the values are only moderately elevated in alcoholic hepatitis and do not reflect the degree of liver cell necrosis. Ornithine carbamyl transferase activity reflects liver cell necrosis more reliably than do the activities of transaminases, but its determination procedure is cumbersome. Persistence of elevated levels of plasma gamma-glutamyl transpeptidase (γ-GTP) despite abstinence from alcohol indicates underlying liver disease, but there are considerable overlaps between serum γ-GTP levels in patients with and without significant necrosis. Measurement of glutamate dehydrogenase (GDH) activity can discriminate between patients with and without alcoholic hepatitis, and falsely elevated levels in the absence of necrosis are uncommon in alcoholics. None of the enzyme activities reflects the stage of disease. Alcoholic hepatitis, pericentral sclerosis, and elevated GDH levels appear to be the most promising markers of progressive alcoholic liver injury.

7851 PLASMA AMINO ACID ABNORMALITIES IN THE ALCOHOLIC: RESPECTIVE ROLE OF ALCOHOL, NUTRITION, AND LIVER INJURY. (Eng.) Shaw, S.; Lieber, C. S. (Bronx Veterans Admin. Hosp., 130 W. Kingsbridge Rd., Bronx, NY 10468). *Gastroenterology* 74(4):677-682; 1978.

To evaluate the respective roles of alcohol consumption, nutrition, and liver injury in producing plasma amino acid abnormalities in the alcoholic, the levels of plasma amino acids were measured in 56 alcoholics with varying degrees of liver injury and nutritional status in 32 nonalcoholics with liver injury, and in 20 well-nourished nonalcoholic patients without history of liver or gallbladder disease. In addition, plasma amino acid levels were measured in baboons fed ethanol as 50% of total calories (a model system with precise dietary control). In 13 alcoholics with prolonged dietary protein deficiency (<56 g/day for >2 weeks), the levels of valine (val), leucine (leu), and isoleucine (isl) were significantly lower ($p<0.01$, $p<0.02$, and $p<0.05$, resp.) than in 15 alcoholics with short-term or no deficiency. In 12 alcoholics sampled after 1-4 days of abstinence, the level of α-amino-*n*-butyric acid (AANB) was significantly ($p<0.02$) increased, and there was a tendency toward increased levels of val, leu, and isl compared to 12 alcoholics of comparable nutritional status sampled after 5 or more days of abstinence. Consumption by three alcoholics of 2,000 kcal alcohol with an adequate diet for 2-4 weeks produced a significant increase in the levels of AANB ($p<0.001$) and isl ($p<0.05$) and marked increases in the levels of leu and val; 1-2 weeks after the withdrawal of alcohol, all the measured parameters fell to levels not significantly different from those of the initial control period. When plasma amino acid levels were measured longitudinally in baboons fed alcohol as 50% of total calories for up to 1-4 yr, the levels of branched-chain amino acids (BCAA) and AANB were slightly but significantly increased by 8-12 weeks ($p<0.02$ for leu and $p<0.001$ for AANB) and markedly increased by 27-47 weeks and 1-4 yr ($p<0.001$ at both times for both parameters). Moderate liver injury in either patients or baboons did not significantly affect plasma BCAA or AANB levels. In alcoholics with severe liver injury (cirrhosis and portal hypertension) who underwent nutritional repletion, there were significant decreases in the plasma levels of leu, isl, and val ($p<0.001$, $p<0.001$, and $p<0.01$, resp.) compared to alcoholics with minimal liver injury who underwent similar repletion. The results show that the plasma amino acid levels in alcoholics are affected by at least three factors: protein intake, alcohol consumptio and severity of liver injury.

Cirrhosis

57 PRIMARY BILIARY CIRRHOSIS IN MOTHER AND
DAUGHTER. (Eng.) Fagan, E.; Williams,
; Cox, S. (King's Coll. Hosp. and Medical Sch.,
ndon SE5, England). *Br. Med. J.* 2(6096):1195;
77.

e case reports of a mother and daughter in whom
vironmental factors seemed to play an important
rt in the pathogenesis of primary biliary cir-
osis are presented. The propositus, a 43-yr-old
man who had been in Singapore from 1964 to 1966,
esented with hepatomegaly and melena. She had
perienced abdominal discomfort and flatulence
ereafter and had noticed intermittent pruritus
nce 1974. Antinuclear antibodies, smooth muscle
tibodies, rheumatoid factor, cold agglutinins,
d hepatitis B surface antigen were not present.
ver biopsy showed a typical pattern of biliary-
pe cirrhosis. The patient's mother presented at
e age of 69 yr with melena. She complained of
vere long-standing Raynaud's phenomenon. She
d been separated from her daughter for 1 yr in
64, but she then rejoined her in Singapore in
65. Liver function tests were abnormal, and
rices were present. Over the next 5 months, she
veloped pruritus and further melena and hema-
mesis. Ascites and a cirrhotic liver were found
laparotomy, and the findings on biopsy were con-
stent with primary biliary cirrhosis. The patient
ed despite a portacaval shunt. Only the mother
d daughter in this family continued to live to-
ther, and this, together with the fact that they
esented with primary biliary cirrhosis within 5
of each other, suggests that an environmental
ctor, probably interacting with genetic compo-
ts, may have been of importance in initiating
e duct destruction.

8 INSULIN RESISTANCE AND BLOOD GLUCOSE RE-
PLACEMENT RATES IN LIVER CIRRHOSIS: STUD-
WITH ^{14}C-GLUCOSE. (Ger.) Adlung, J.; Kelch,
Peters, J.; Grazikowske, H. (Medizinische
hschule, Kronsforder Allee 71/73, D-2400 Lubeck,
Germany). *Z. Gastroenterol.* 15(9):553-564; 1977.

od glucose replacement and insulin resistance
e studied in 21 patients with inactive liver
rhosis, 8 patients with chemical diabetes, 11
ients with overt senile diabetes, and 35 normal
jects by the i.v. injection of 0.5 g/kg glucose
taining ^{14}C-labeled glucose. Impaired glucose
erance was found in 71% of the cirrhotic pa-
nts. The insulinogenic index was elevated in
patients with liver cirrhosis and normal glu-
e tolerance, and it was normal or below normal
those with carbohydrate intolerance, as well as
diabetics. The decrease in the specific activ-
of glucose, expressing the supply of nonlabeled
cose to the body pool, was much more rapid in
ients with carbohydrate intolerance, either
atogenic or not, than in carbohydrate-tolerant
ients when compared at equal glucose concentrations. Moreover, all patients with deteriorated glucose tolerance exhaled less $^{14}CO_2$ than did glucose-tolerant subjects. Consequently, diabetes in chronic liver disease displays the same abnormalities as diabetes in obesity with respect to liver glucose supply and glucose oxidation. In both conditions, diminished glucose assimilation is usually the result of reduced elimination and increased supply. Therefore, impaired hepatic uptake of glucose cannot be implicated as a single cause of hepatogenic diabetes.

7859 GROUP-SPECIFIC COMPONENT [Gc] LEVELS IN CHRONIC LIVER DISEASE. (Eng.) Mihas, A. A.; Hirschowitz, B. I. (Div. Gastroenterology, Univ. Alabama, Birmingham, AL 35294). *J. Med.* 9(2):109-115; 1978.

To elucidate the biologic function of group-specific component (Gc), serum Gc concentrations were measured by radial immunodiffusion in 72 patients with chronic liver disease and correlated with liver function measurements. Gc, an alpha-2-globulin (50,000 daltons) synthesized in the liver, is the proposed vitamin D transport protein. In all cases (liver cirrhosis, 28; metastatic liver disease, 15; chronic active hepatitis [CAH], 11; biliary tract disease, 18), diagnosis of liver disease was confirmed by needle biopsies. Liver function tests included measurements of the serum levels of bilirubin, SGOT, alkaline phosphatase, albumin, and bile acids (SBA). Low Gc values correlated with low serum albumin levels and high Gc levels correlated with high SGOT levels. An inverse relationship was observed between SBA and Gc levels, indicating possible Gc globulin involvement in bile acid transport. Patients with liver cirrhosis and those with metastatic liver disease showed significantly ($p<0.01$) lower serum Gc levels than did controls. Patients with CAH, without histologic evidence of established cirrhosis, had serum Gc levels significantly ($p<0.01$) higher than the control group (58.0 ± 6.0 versus 44.0 ± 6.0 mg/dl). When the biliary tract disease group was subdivided into patients with and without bone disease, all seven patients with severe bone disease were found to have significantly ($p<0.01$) lower serum Gc levels (27.0 ± 3.0 mg/dl) than did the controls. The authors suggest that low Gc values may decrease vitamin D_3 transport and so contribute to the osteodystrophy of obstructive liver disease.

7860 INCREASED FACTOR VIII COMPLEX AND DEFECTIVE RISTOCETIN-INDUCED PLATELET AGGREGATION IN LIVER DISEASE. (Eng.) Castillo, R.; Maragall, S.; Rodes, J.; Clemente, C.; Profitos, J.; Ordinas, A. (Hospital Clinico y Provincial, Barcelona, Spain). *Thromb. Res.* 11(6):899-906; 1977.

To elucidate the nature of hemostatic defects in liver cirrhosis, levels of the factor VIII procoagulant activity (VIII:C), the factor VIII-related antigen (VIIIR:AG), and factor VIII von Willebrand activity (VIIIR:WF) were assayed in 23 patients with advanced cirrhosis and in normal subjects. In 12 of these patients, the Ristocetin-induced aggregation of washed platelets in the presence of normal platelet-poor plasma (PPP) was also studied; in 5/12 patients bovine factor VIII-induced aggregation was studied. In normal subjects, the average plasma VIII:C level was 91.66 ± 22.97 U/dl, while in cirrhotic patients it was 147.56 ± 103.74 U/dl. The mean value of VIIIR:AG was 90.26 ± 25.05 U/dl in normal subjects and 633.04 ± 259.79 U/dl in cirrhotic patients ($p<0.001$). The mean value of VIIIR:WF was 330.00 ± 215.00 U/dl in cirrhotic patients compared to 104.93 ± 12.38 U/dl in normal subjects. The degree of correlation between the three variables was high in normal subjects ($r \sim 0.80$) but low in cirrhotic patients ($r \sim 0.1$). The initial velocity of the Ristocetin-induced aggregation of washed platelets with normal PPP was diminished in each case compared to the results obtained with a control system of normal platelets containing the same number of platelets. The bovine factor VIII-induced platelet aggregation, however, was normal. These data confirm that, in cirrhotic patients, the factor VIII elevation is an increase of the whole protein, most likely caused by hepatic damage, not merely a raising of the procoagulant activity.

7861 THE ROLE OF THE FALSE NEUROTRANSMITTERS, OCTOPAMINE AND PHENYLETHANOLAMINE, IN HUMAN HEPATIC ENCEPHALOPATHY.

(Eng.) Cangiano, C.; Calcaterra, V.; Cascino, A.; Fanelli, F. R.; Capocaccia, L. (III Clinica Medica, Policlinico Umberto I, Universita di Roma, Roma, Italy). *Rend. Gastroenterol.* 9(3):189-193; 1977.

To determine whether the accumulation of octopamine and phenylethanolamine (PEA) are involved in the etiology of hepatic encephalopathy, these false neurotransmitters were measured by a radioenzymatic assay in the plasma of healthy volunteers and in cirrhotic patients with and without encephalopathy. Octopamine levels were determined in plasma obtained from venous and arterial blood, whereas PEA was determined only in venous blood plasma. There were 23 normal subjects, 80 cirrhotic patients without liver coma, 27 cirrhotics who were in grades 1 or 2 hepatic coma, and 18 cirrhotics in grades 3 or 4 hepatic coma. Octopamine levels increased in the presence of chronic hepatic disease and at the onset and during the evolution of hepatic encephalopathy. In plasma from venous blood, the differences between the cirrhotic patients without coma and those in grade 1 or 2 hepatic coma ($p<0.005$) and between those in grade 1 or 2 and those in grade 3 or 4 coma ($p<0.001$) were statistically significant, whereas the difference between the healthy controls and the cirrhotic patients without coma was at the limit of the statistical difference ($0.1<p<0.05$). The octopamine level in plasma from arterial blood was significantly greater ($p<0.005$) in cirrhotic patients without coma than in the normal controls,
but no other significant differences were seen.
The mean arterial values of octopamine were hig
than those of venous measurements in all groups
except in patients in grades 3 or 4 hepatic com
There was a good correlation between the venous
PEA levels and the presence of liver cirrhosis
and grade of hepatic coma. Differences betweer
controls and cirrhotics without coma, between
cirrhotics without coma and those with grades
or 2 coma, and between those with grades 1 or
coma and those with grades 3 or 4 coma were al
significant ($p<0.05$, $p<0.05$, and $p<0.02$, resp.
There was a good correlation ($r=0.50$, $p<0.01$)
between venous ammonia and octopamine levels i
the 45 patients in whom these measurements were
taken simultaneously. These data indicate tha
plasma PEA and octopamine levels increase in
hepatic encephalopathy and that these increase
are correlated with the intensity and evolutior
the neurological disorders.

7862 HEPATIC ARTERIOPORTAL FISTULA RELATE A LIVER BIOPSY.

(Eng.) Baer, J. W.
(421 W. 113th St., New York, NY 10025). *Gastro*
intest. Radiol. 2(3):297-299; 1977.

A patient with hepatic artery portal fistula pr
senting with bleeding esophageal varices 5 mont
following a liver biopsy for cirrhosis is prese
The patient was a 52-yr-old alcoholic man with
vious evidence of cirrhosis and portal hyperter
A single pass with a 1.4-mm internal diameter
ghini needle was done. A sizeable portal vein
not identified in the specimen, although a port
triad and a central vein were seen. There were
immediate postbiopsy complications. Bleeding
ageal varices 5 months later were successfully
treated with pitressin. A celiac arteriogram
in preparation for a mesocaval shunt showed an
hepatic arterioportal vein fistula within the
lobe of the liver, enlarging the right branch
the portal vein. There was hepatopetal portal
within the liver. The main portal vein as wel
the branch to the left lobe of the liver were
visualized as a result of filling from the spl
vein on delayed films. The venous phase of th
superior mesenteric arteriogram showed filling
the main portal vein, the branch to the left l
and the umbilical vein sequentially. An end-t
portacaval shunt was performed since the intra-
hepatic portal vein was already "arteriolized,
but the patient did poorly because of closure
the shunt.

7863 SMALL NODULAR LIVER CIRRHOSIS WITH M PORTAL HYPERTENSION DUE TO VITAMIN A INTOXICATION RESULTING FROM PSORIASIS TREATMEN

(Ger.) Fleischmann, R.; Schlote, W.; Schomeru
H.; Wolburg, H.; Castrillon-Oberndorfer, W. L.
Hoensch, H. (Medizinische Universitatsklinik,
fried-Muller-Strasse, 7400 Tubingen, W. German
Dtsch. Med. Wochenschr. 102(45):1637-1640; 197

A 36-yr-old man developed small nodular liver
rhosis and marked portal hypertension with ble
esophageal varices 3.5 yr after a 7-week treat

th vitamin A (total dose 7 x 10^7 IU p.o., maximum
ily dose 1.2 x 10^6 IU) for psoriasis vulgaris.
ere was no increase in the serum vitamin A level
5 yr after the treatment, but increased deposits
vitamin A were found in the perisinusoidal lipid
orage cells (Ito cells) by fluorescence spectro-
otometry and electron microscopy of the liver
opsy specimen. Thoracoabdominal subdiaphrag-
tic fundectomy, resection of the lower seg-
nt of the esophagus, splenectomy, proximal
lective vagotomy, and pyloroplasty were per-
rmed. The patient is in good condition 2 months
ter surgery; the liver function tests are nearly
rmal.

64 THYROID FUNCTION IN CIRRHOTIC PATIENTS:
HORMONE BALANCE IN 24 PATIENTS WITH EDEMA-
US-ASCITIC DECOMPENSATION. (Fre.) Schmitt, B.;
ouretti, M. (Hopital Haut-Leveque, F 33604 Bor-
aux Pessac, France). *Nouv. Presse Med.* 6(35):
28-3229; 1977.

24 patients with cirrhosis accompanied by edema-
us ascites and decompensation, radioimmunoassays
re performed for circulating 3,5',3'-triiodothy-
nine (T3r), 3,5,3'-triiodothyronine (T3), thyrox-
e (T4), free thyroxine (IT4), and thyroid-stimu-
ting hormone (TSH). The values obtained were
mpared with established normal values. The levels
T3 were significantly lower ($p<0.001$) and the
vels of T3r significantly higher ($p<0.001$) in the
compensated cirrhotic patients; no significant
fference was observed in values for T4, IT4, or
H. There appears to be an alteration in the con-
rsion of T4 to T3 that causes an increase in
ripheral T3r at the expense of T3. This hormonal
dification is responsible for the symptoms of
pothyroidism observed in these cirrhotic patients.
is suggested that measurement of levels of T3 and
r may be used as a means of surveillance of pa-
ents under treatment for decompensated cirrhosis.

55 INTRAABDOMINAL BLEEDING FROM VARICEAL
VESSELS IN CIRRHOSIS. (Eng.) Shapero,
F.; Bourne, R. H.; Goodall, R. G. (Sunnybrook
ical Center, 2075 Bayview Ave., Toronto, Ontario,
ada). *Gastroenterology* 74(1):128-129; 1978.

The case of a cirrhotic patient who developed intraabdominal bleeding from variceal vessels is presented. The patient, a 39-yr-old alcoholic man, developed increased abdominal girth, abdominal pain, and stools positive for occult blood. At laparotomy, hemoperitoneum was present, and the bleeding was found to originate from variceal vessels in the peritoneum lateral to the ascending colon. Hemostasis was obtained with suturing, but the patient died postoperatively. Precipitous abdominal swelling associated with abdominal pain in a cirrhotic patient should alert the physician to the possibility of hemoperitoneum; it demands immediate paracentesis.

7866 DETERMINANTS OF ASCITIC FLUID PROTEIN IN CIRRHOSIS [Abstract]. (Eng.) Hoefs, J. (Dept. Medicine, Univ. Southern California, Los Angeles, CA). *Clin. Res.* 26(2):151A; 1978.

7867 HYDROCHLORIC ACID-INDUCED SECRETIN RELEASE, AND HALF-LIFE OF EXOGENOUS SECRETIN IN PATIENTS WITH LIVER CIRRHOSIS [Abstract]. (Eng.) Pelletier, M. J.; Chayvialle, J. A.; Descos, F.; Descos, L. (INSERM, U-45, Hopital Edouard-Herriot, 69374, Lyon, France). *Ir. J. Med. Sci.* 146(Suppl. 1):3; 1977.

7868 EFFECT OF AGE AND CIRRHOSIS ON THE DISTRIBUTION AND ELIMINATION OF CHLORDIAZEPOXIDE (LIBRIUM®) [Abstract]. (Eng.) Roberts, R. K.; Wilkinson, G. R.; Branch, R. A.; Schenker, S. (Vanderbilt Univ. Sch. Medicine, Nashville, TN). *Gastroenterology* 73(5):1243; 1977.

LIVER AND BILIARY TRACT

Gallbladder and Biliary Tract Diseases

59 PROSPECTIVE STUDY OF THE FIRST 197 ENDO-
SCOPIC RETROGRADE CHOLANGIOPANCREATICO-
PHIES PERFORMED IN BASEL (1973-1975). (Ger.)
noulli, R.; Faust, H.; Gyr, K.; Thurnherr, N.;
ishanslin, W.; Stalder, G. A. (Kantonsspital,
4004 Basel, Switzerland). *Schweiz. Med. Wochen-*
r. 107(37):1287-1291; 1977.

prospective evaluation of the first 197 endoscopic retrograde cholangiopancreaticographies (ERCP) performed in Basel during the 1973-1975 period is presented. It was possible to visualize the pancreatic duct, common bile duct, or both in 144/197 cases; the failure was due to the patient and/or instrument in 18/53 cases and to the examiner in 35. One hundred forty-two investigations were evaluable with respect to the definitive diagnosis. ERCP was correct in 101 cases, false in 10, and furnished additional information in 31 cases. Acute pancreatitis, chronic pancreatitis, pancreatic pseudocysts, choledocholithiasis, carcinoma and sclerosis of the papilla, carcinoma and stenosis of the bile ducts, fistula of the cystic duct, Caroli's disease, hepatitis, liver cirrhosis, functional disorders, villous adenoma of the duodenum, and other diseases were the definitive diagnoses in the 101 cases that were correctly diagnosed by ERCP. The early complications of ERCP included one lethal sepsis in obstructive jaundice, aggravation of chronic recurrent pancreatitis in two cases, and abdominal complaints in five. Insufficient distinction between acute and chronic pancreatitis was the main cause of disagreement with the final diagnosis in the 10 discordant cases. It is difficult to differentiate between chronic pancreatitis and pancreatic carcinoma. The examiner failure showed a declining tendency as the experience of the examiner increased. The findings indicate that ERCP should be limited to regional hospital centers, and be performed only in cases with well-defined indications.

7870 THERAPEUTIC ENDOSCOPIC RETROGRADE CHOLANGIOGRAPHY. (Ger.) Safrany, L.; Kautz, G.; van Husen, N.; Weitemeyer, R. (Reinhard-Nieter-Krankenhaus, D-2940 Wilhelmshaven, W. Germany). *Langenbecks Arch. Chir.* 345:267-273; 1977.

The results of endoscopic papillotomy performed in 545 patients were evaluated. The papillotomy was successful in 516 patients; they included 405 patients with choledocholithiasis, 97 with organic papillary stenosis, 12 with tumors (carcinomas, papillomas, and adenomyomas) of the papilla, and 2 with stones of the pancreatic duct. The complications included hemorrhage in 11 cases, retroperitoneal perforation in 10, pancreatitis in 6, cholangitis with incarcerated stone in 11, and incarceration of the Dormia cage in 2; laparotomy was necessary in 11 of these 38 patients. The mortality of the endoscopic papillotomy was 5/545; 4 patients died from cholangitis and 1 from pancreatitis. Advanced age, poor general condition, cholangitis, chronic pancreatitis, juxtapapillary diverticulum, and past Billroth II gastric resection are not contraindications of endoscopic papillotomy. It is becoming increasingly evident that endoscopic papillotomy is a valid alternative to reoperation in many cases of choledocholithiasis.

7871 A COMPARISON OF INTRAVENOUS AND INFUSION CHOLANGIOGRAPHY WITH INTRAOPERATIVE AND TOMOCHOLANGIOGRAPHY. (Ger.) Grauthoff, H.; Thelen, M.; Peters, M. (Radiologische Universitatsklinik, 5300 Bonn-Venusberg, W. Germany). *Fortschr. Geb. Roentgenstr. Nuklearmed.* 127(6):575-577; 1977.

The diagnostic value of preoperative i.v. or infusion cholangiography (IC), intraoperative cholangiography (IOC), and additional tomocholangiography (TC) was studied in 72 patients with papillary stenosis (38), choledocholithiasis (16), and prepapillary stones (20). The intraoperative diagnosis of papillary stenosis was confirmed in 33/38 cases by IOC, in 28/38 cases by IC, and in 19/24 cases by TC. Choledocholithiasis was correctly diagnosed in 13/16 cases by IC, in 9/11 cases by TC, and in 9/16 cases by IOC. Papillary stenosis was diagnosed correctly in 15/20 cases by IC, in 9/16 cases by TC, and in 16/20 cases by IOC. The findings indicate that stenosis of the papilla is diagnosed most reliably by IOC. Intravenous and infusion cholangiography were of equal value; they each provided less information than did the intraoperative examination. IC was significantly better for the diagnosis of choledocholithiasis than was IOC, and tomography furnished no additional information. Stones of papilla are diagnosed most reliably by IOC, while preoperativ TC resulted in a loss of information.

7872 INDICATIONS FOR ENDOSCOPIC PAPILLOTOMY. (Eng.) Classen, M.; Ossenberg, F. W. *In: The Sphincter of Oddi. Proceedings of the Third Gastroenterological Symposium, Nice, June 8 1976.* (Basel: S. Karger): 228-231; 1977.

Current knowledge concerning the indications for endoscopic papillotomy is reviewed, and the autho experience with this procedure is presented. A benign papillary stenosis was removed or at least improved by this procedure in all 10 patients in whom it was performed. Common duct stones were removed completely in 86% of 85 patients. Severe complications were observed in 5.6% of the patie who underwent endoscopic papillotomy. Although none died, a mortality rate of 1-1.5% has been su gested by other studies. The use of endoscopic papillotomy in the treatment of isolated papilla stenosis should be limited to cases in which the following have been demonstrated: clinical sign and laboratory diagnostics of cholestasis, radiological demonstration of enlarged extra- and int hepatic bile ducts, and increased duodenobiliary pressure gradient. The indications for the endoscopic removal of common duct stones are (1) retained or recurrent common duct stones after preceding operations or (2) patients who are high operative risks.

7873 BILIARY BACTERIOLOGY BASED ON INTRAOPE ATIVE BILE CULTURES. (Eng.) Delikari P. G.; Michail, P. O.; Klonis, G. D.; Haritopoul N. C.; Golematis, B. C.; Dreiling, D. A. (First Dept. Surgery, Univ. Athens, 66 Ipirou St., Athe 109, Greece). *Am. J. Gastroenterol.* 68(1):51-55 1977.

Bile cultures taken during 174 extrahepatic biliary tract operations were studied to examine the role of bacteria in postoperative infections and the factors involved in the development of septic complications. There were 45 positive bi cultures (26%). *Escherichia coli* was the most common organism, and was recovered in 21 cases; *Klebsiella* was second in frequency, being found 13 cultures. There was no sex predominance in the positive bile culture group, there being 22

and 23 women. There was an increasing per-
age of positive bile cultures with advancing
regardless of the underlying disease. The
est incidence of positive bile cultures oc-
ed in patients with acute cholecystitis (9/9
s), as compared with the incidence in chol-
sis (16/46) or with noncholestatic patients
119). Septic complications in the patients
a negative bile culture were rare (1.5%),
eas the rate among the patients with a posi-
culture was 33.3%. Since septic complications
be the result of intraoperative contamination
the infected bile, an argument is presented
prophylactic preoperative antibiotic adminis-
ion as well as for routine culture of bile
he time of surgery.

ERCP IN THE DIAGNOSIS AND MANAGEMENT OF
PERIAMPULLARY CARCINOMA. (Eng.) Salmon,
; Rey, J. F.; Baddeley, H.; Schiller, K. F.
Davies, J.; MacKenzie, E.; Read, A. E. *In:*
Sphincter of Oddi. Proceedings of the Third
oenterological Symposium, Nice, June 8-9, 1976.
l: S. Karger): 111-114; 1977.

ience with endoscopic retrograde cholangio-
eatography (ERCP) in the diagnosis of peri-
lary carcinoma is presented. Among 535
nts who underwent diagnostic ERCP between
and 1976, 14 patients were diagnosed as
g carcinoma, and this was confirmed in 11.
of the 11 patients had symptoms less than
ths, 5 less than 4 weeks, and 2 less than
ks. In addition, nine presented with jaun-

s procedure was performed.

A NEW ENDOPROSTHESIS FOR NONOPERATIVE IN-
TUBATION OF THE BILIARY TRACT IN MALIG-
BSTRUCTIVE JAUNDICE. (Eng.) Burcharth, F.
fte Hosp., Copenhagen, Denmark). *Surg. Gyn-*
Obstet. 146(1):76-78; 1978.

previously described method for percutaneous
epatic intubation under local anesthesia
vestigated in 19 patients having inoperable
y tract tumors or presenting as prohibitively
perative risks. The method is carried out
ing diagnostic percutaneous transhepatic
giography, and involves the insertion of an
osthesis under fluoroscopic control. A
ire is passed from a punctured peripheral
y duct into the biliary tract and manipulated
he obstruction into the duodenum. The endo-
esis, a radiopaque polyethylene catheter
ide holes, is pushed forward through the ob-
ion with an introducer until the distal end
ow the obstruction and the proximal end is
in the biliary tree above the obstruction. The introducer is connected to a catheter bag and left in the biliary tree for external drainage of bile. Twelve patients had inoperable malignancies, and their obstructive jaundice was treated palliatively with the endoprosthesis. Jaundice disappeared after 2 weeks in nine patients and decreased in five. Among the seven patients who underwent surgery, four still had jaundice when the operation was performed. In six patients with unresectable periampullary tumors, intubation was attempted but proved to be impossible due to advanced stenosis of the tumor. No patient showed signs of cholangitis, bile peritonitis, or bleeding. The median survival time in the 12 patients exclusively treated with endoprosthesis was 61 days. In all patients, jaundice recurred approximately 1 month before death. At autopsy, neither cholascos nor gallstones were found, and all endoprostheses were in the correct position and without sludge obstruction. With extended experience, the endoprosthesis may prove to be a worthwhile alternative to biliodigestive anastomoses in selected patients.

7876 RHABDOMYOSARCOMA OF THE BILE DUCTS. (Eng.) Nagaraj, H. S.; Kmetz, D. R.; Leitner, C. (Univ. Louisville Sch. Medicine, Louisville, KY 40201). *J. Pediatr. Surg.* 12(6):1071-1074; 1977.

The case of a child with a rhabdomyosarcoma of the bile ducts is presented. The patient, a 4.5-yr-old boy, had recurrent jaundice, fever, abdominal pain, and hepatomegaly. Ultrasonography of the liver disclosed hepatomegaly with probable dilatation of bile ducts. Two avascular areas close to the porta hepatis were demonstrated on selective celiac arteriography. An operative cholangiogram showed a small cystic duct and a dilated common duct that readily emptied into the duodenum. However, no dye could be refluxed into the proximal duct. Several soft yellow-tan polypoid masses were found in the common duct. The major portion of the tumor arose from the common hepatic duct, and the common duct, common hepatic duct, gallbladder, and cystic duct were resected. Ultrastructural examination of the tumor disclosed immature skeletal muscle fibers, exhibiting myofibril formation. A liver biopsy specimen showed biliary cirrhosis and was free of tumor. The distal part of the common bile duct was tumor-free. The patient has had no evidence of tumor or local recurrence for the past 9 months, during which time he has received alternate doses of vincristine and actinomycin D.

7877 SCLEROSING CHOLANGITIS AND PRIMARY BILIARY CIRRHOSIS--A DISEASE SPECTRUM? (Eng.) Fee, H. J.; Gewirtz, H.; Schiller, J.; Longmire, W. P., Jr. (Univ. California Los Angeles Sch. Medicine, Los Angeles, CA). *Ann. Surg.* 186(5):589-593; 1977.

A study was made retrospectively of 21 patients with primary sclerosing cholangitis (PSC) and 14 with primary biliary cirrhosis (PBC) in which there was absence of choledocholithiasis, previous bile duct surgery, malignancy, or cholestatic jaundice from drug or viral hepatitis and presence of progressive obstructive jaundice and of thickening and fibrosis in the affected intra- or extrahepatic system. The average age of onset was 40-50 yr in men and 20-40 yr in women with PSC and 50 yr in men and 40-60 yr in women with PBC. The major presenting complaints were jaundice and pruritus in PSC and pruritus, jaundice, abdominal pain, and lethargy in PBC. There were 47% and 21% men with PSC and PBC, resp., in this series. Laboratory findings in both diseases are similar: bilirubin and alkaline phosphatase levels are elevated (markedly in PSC and moderately in PBC), cholesterol levels were elevated in many patients, and eosinophilia was noted (in 7/21 PSC and 3/14 PBC patients). The distinction between PSC and PBC is often difficult; PSC had a slightly higher incidence of associated autoimmune disease, a greater hyperbilirubinemia (usually mixed), a more marked incidence of eosinophilia, and a more pronounced hypercholesterolemia. Of the 21 PSC patients, 3 had thyroiditis, 3 had ulcerative colitis, 1 had granulomatous colitis, and 6 had xanthomata; of the 14 with PBC, 1 had Hashimoto's thyroiditis, 2 had idiopathic myopathies, 1 had retroperitoneal fibrosis, and 1 had xanthalasma. Six of the 21 patients with PSC had associated, histologically proven PBC as well. Choleretics and cholestyramine were more effective than steroids or immuran in treatment. Treatment by T-tube drainage involved a considerable risk of infection, so that cholangitis was a frequent cause of morbidity. The prognosis of both PSC and PBC is usually grave and life expectancy difficult to determine; survival time did not correlate with initial laboratory findings or associated diseases. The mean time from symptoms to death was 9.5 yr and 2.5 yr in PBC and PSC, resp., and the causes of death were hepatic failure (4 in PBC, 3 in PSC), hepatorenal syndrome (1 in each disease), pericarditis (1 in PSC), cerebrovascular accident (1 in PSC), ascending cholangitis (1 in PSC), and unknown (1 in PBC). Etiologically, no organism was consistently found in the bile, and several samples were sterile. These two diseases may represent varying degrees of response to a common etiological agent.

7878 ABSORPTION AND METABOLISM OF CHENODEOXYCHOLIC ACID IN MAN.

(Eng.) v. Berge-Henegouwen, G. P.; Hofmann, A. F.; Thistle, J. L.; Schalm, S. W.; Cowen, A. E. *In: Bile Acid Metabolism in Health and Disease. Proceedings of the IV Bile Acid Meeting held at the Hilton Hotel, Basel, Switzerland, October 11-12, 1976.* (Baltimore: University Park Press): 157-159; 1977.

The pharmacokinetics of chenodeoxycholic acid were studied in healthy volunteers and in gallstone patients on regular chenodeoxycholic acid therapy. Intraduodenally instilled solutions of chenodeoxycholate were absorbed completely at loads varying from 25 to 400 mg in a 50-cm segment of jejunum. By gas-liquid chromatography, the concentration of unconjugated chenic acid in peripheral blood rose to a peak (10-50 μM) within 10 min. Chenic acid was also absorbed completely when administered p Hepatic chenic acid clearance was constant for doses from 25 to 400 mg. First-pass hepatic cle ance of chenic acid averaged 62% and was conside ably greater for chenyl conjugates. Chenic acid appeared in peripheral blood in the unconjugated form; it was rapidly conjugated in the liver and excreted into bile.

7879 DISSOLUTION OF GALLSTONES LEFT IN THE COMMON BILE DUCT.

(Ger.) Thiele, H. (Chirurgische Klinik, Klinikum Mannheim, Theodor Kutzer-Ufer, D-6800 Mannheim-1, W. Germany). *La enbecks Arch. Chir.* 344(2):123-129; 1977.

Conservative methods were used to remove residua gallstones from the common bile duct after chole cystectomy and inspection of the common bile duc in eight women aged 30-73 yr. Heparin infusion was used to dissolve the gallstones in six patients: complete dissolution was achieved in th cases, the dissolution of the stone was probable but not proved in one case, and the heparin infusion treatment was unsuccessful in two cases. Gallstones with high cholesterol content were di solved most easily. The gallstones were dissolv successfully in one patient by means of an ether chloroform mixture, but the treatment had to be stopped because of rausch. Treatment with hepar and sodium cholate was unsuccessful in one patie In case of failure, the stones were removed at relaparotomy.

7880 STONE DISSOLUTION AND THE NATIONAL COO ERATIVE GALLSTONE STUDY.

(Eng.) Scho field, L. J. (Cedars-Sinai Medical Center, 8700 Beverly Blvd., Los Angeles, CA 90048). *Am. J. Dig. Dis.* 22(12):1115-1116; 1977.

A progress report of the National Cooperative Ga stone Study (NCGS) is presented. The NCGS is a randomized, controlled, double-blind, cooperati clinical trial in which the primary aim is to determine the efficacy and safety of chenodeoxycholic acid (CDC) in gallstone dissolution. Its secondary aims are to identify specific determi of efficacy and safety, study the frequency and management of recurrence after dissolution, and investigate relevant basic mechanisms. Accessi of patients to the initial (liver biopsy) study was completed in 1976, at which time the main clinical study was initiated with Food and Drug Administration approval. This study includes 1 patients randomized to receive either 375 or 75 mg/day of CDC. These patients will undergo pre and post-treatment liver biopsies in addition t the same frequent clinical and laboratory patie safety monitoring procedures of the main study. In the main study, 900 patients will be randomi to receive either 375 or 750 mg/day of CDC or placebo. So far, about 500 patients have enter the main study. The NCGS, under careful scruti is progressing satisfactorily toward definitive conclusions regarding the efficacy and safety o CDC.

81 EFFECT OF INCREASED DIETARY FIBER ON BILI-
ARY CHOLESTEROL IN PATIENTS WITH GALL-
ONES. (Eng.) McDougall, R. M.; Walker, K.;
urston, O. G. (Univ. Alberta Hosp., Edmonton,
berta, Canada). *Surg. Forum* 28:416-418; 1977.

study the underlying mechanisms in cholesterol
olelithiasis, the effect of increased dietary
ber in the form of bran on biliary lipids, bile
id pool size, and individual bile acid ratios
s studied in seven patients with radiolucent
llstones in a functioning gallbladder and in
ne healthy volunteers. Bile specimens were col-
cted before and after a 4-week period, during
ich the subjects ate 50 g of a bran cereal daily
one or two servings. Initially, bile was super-
turated with cholesterol in the seven patients
d became unsaturated in all seven with increased
etary fiber ($p<0.02$). In controls, bile was un-
turated with cholesterol before and after bran.
e total bile acid pool was reduced in gallstone
tients as compared with that in controls and did
t change in either group with bran (mean pool
zes, 1.66 versus 2.51 g; $p<0.05$). The proportion
deoxycholic acid in the bile acid pool was in-
eased initially in patients with gallstones in
mparison with controls (mean 32.0 versus 19.0%;
0.05). The proportion of the bile acid pool
rmed by deoxycholic acid declined in both groups
th bran (gallstones, 32.0% to 22.9%; controls,
.0% to 17.0%; $p<0.05$ for the two groups combined).
e data indicate that increased dietary fiber in
tients with gallstones causes the return to an
saturated state of bile supersaturated with cho-
sterol. These data suggest that the reduced bile
id pool size seen in gallstone patients may be
e to impaired gallbladder function or bile dis-
acement by stones, since reduced pool size could
restored in the patients with gallstones by
patic bile acid synthesis.

2 ACUTE NON-CALCULOUS CHOLECYSTITIS IN BURNS.
(Eng.) Alawneh, I. (Stadt. Krankenhause,
acelsusstrasse 1-9, 3320 Salzgitter-Bad 51, W.
many). *Br. J. Surg.* 65(4):243-245; 1978.

en burned patients who developed acute chole-
titis were studied. The time of onset of symp-
s varied between 10 and 37 days after the in-
y. Jaundice was present in five patients, and
e cultures were positive in six patients. There
e six men and one woman; five patients were 28
40 yr old, and the other two were 56 and 69 yr.
lecystectomy was performed in all patients, and
patient died. It is suggested that the cause
post-burn cholecystitis is traumatic and septic
ck, with consequent biliary stasis.

3 CHOLESTASIS ASSOCIATED WITH CENTRAL IN-
TRAVENOUS NUTRITION IN INFANTS. (Eng.)
wn, M. R.; Putnam, T. C. (Genesee Hosp., 224
xander St., Rochester, NY 10467). *N.Y. State
Med.* 78(1):27-30; 1978.

case reports of two infants who developed severe intrahepatic cholestasis during central intravenous nutrition are presented. The first infant underwent a 20-cm ileal resection for atresia with meconium peritonitis (day 1 of life) but developed necrotizing enterocolitis by day 18. The second infant (1 kg; premature) did well until massive resection of the small intestine was required on day 37 of life for necrotizing enterocolitis. The first infant developed elevated levels of peripheral eosinophils, alkaline phosphatase, and bilirubin. Despite a change to p.o. diet, the bilirubin level increased, stools became acholic, tyrosine and then methionine levels became elevated, and biopsy revealed hepatocellular and canalicular cholestasis. He did not respond to phenobarbital (5 mg/kg/day for 1 week) or to cholestyramine (1 g/day) plus prednisone (5 mg/day) between day 57 and the 4th month of life, at which time the stools gradually became yellow and liver function tests returned to normal. During his 5th month, severe respiratory problems arose and he continued to have asthma and other allergic symptoms. The second infant had *Klebsiella* and *Candida* in tracheal aspirates before the institution of parenteral nutrition. When the liver and spleen became enlarged, p.o. feeding was reinstituted, but the patient developed recurrent apnea, persistent acidosis, hemolytic anemia, cardiovascular arrests, and elevated methionine and tyrosine levels. Phenobarbital (5 mg/kg, i.m.) did not lower the bilirubin level, and cholestyramine administration caused diarrhea. The infant died of cardiorespiratory arrest, and autopsy revealed micronodular cirrhosis with significant cholestasis and abnormalities in the lungs, brain, and kidneys. Cholestasis associated with parenteral nutrition in infants is probably multifactorial. Drug toxicity, bacterial toxicity, amino acid toxicity, and lack of bile flow stimulation may be possible causes.

7884 ENTEROBILIARY FISTULA AND ERCP. (Eng.)
Ghazi, A. (Beth Israel Medical Center, 10 Nathan D. Perlman Pl., New York, NY 10003). *Am. J. Gastroenterol.* 68(1):81-83; 1977.

A case of ascending cholangitis with a patent enterobiliary fistula in which endoscopic retrograde cholangiopancreatography (ERCP) gave useful diagnostic information is presented. The patient was a 60-yr-old woman who presented with right upper quadrant abdominal pain, nausea, vomiting, fever, and chills for 1 week. She had undergone gallbladder surgery 15 yr previously. Physical examination revealed a palpable right upper quadrant mass and jaundice. Gastrointestinal series revealed that no contrast material entered the biliary tract under fluoroscopic control, but lateral overhead films showed opacification of the biliary tree that revealed a common bile duct dilated to 1.5 cm. The cystic duct and gallbladder did not visualize. No calculi were demonstrated in the common bile duct. ERCP was carried out after the serum bilirubin level had increased from 1.4 mg% to 4 mg% and revealed an enterobiliary fistula with an opening located in the proximal portion of the second part of the duodenum. Cannulation through this opening revealed a common bile duct dilated to 2.5 cm, which contained several large calculi. The cystic duct and gallbladder again did not visualize. Exploratory laparotomy showed acute cholecystitis, cholelithiasis, choledocholithiasis, and choledochoduodenal fistula. A cholecystectomy was carried out, and all calculi were removed from the common bile duct. The T-tube was left in place. The patient made an uneventful recovery. The presence of air in the biliary system is not definite evidence of a well-functioning fistula and does not rule out intraductal biliary pathology. Demonstration of a fistula by barium reflux into the fistula's tract does not necessarily mean that all the pathology that is present within the ductal system has been demonstrated. Hence, ERCP is a useful diagnostic tool.

7885 HEPATOSPLENIC SCINTIGRAPHY IN CHILDREN WITH OBSTRUCTIVE JAUNDICE. (Eng.) Da-Costa, H.; Gandhi, R.; Deshmukh, S.; Puri, K.; Loken, M. (B.A.R.C. and K.E.M. Hosp., Parel, Bombay, India). *Clin. Nucl. Med.* 2(11):381-385; 1977.

Experience using hepatosplenic scintigraphy in 36 children with obstructive jaundice is summarized. Of 11 patients with extrahepatic biliary obstruction, all had choledochal cysts and three also exhibited extrinsic biliary atresia. Liver scans in patients with choledochal cysts showed less than normal radiocolloid radioactivity in the region of the porta hepatis. This finding persisted whether the cysts were palpable or nonpalpable. The left hepatic lobe tended to be prominent in this group of patients, such that the spleen was frequently indecipherable on radiocolloid scans from the abutting left lobe of the liver. ^{131}I-rose bengal (RB) studies were carried out in children suspected of either biliary atresia or choledochal cysts as suggested by the radiocolloid scintiphotographs. Only in two patients was the initially nonradioactive portal region subsequently seen to contain ^{131}I-RB; in both cases, this change was first noticed in the 7-hr scintiphotogram, suggesting that the zone was being gradually filled during the excretory phase and that the abnormality was located along the tract of the common bile duct. No choledochal cyst accumulated RB. The authors stress the necessity for correlation between clinical, laboratory, radiological, and scintigraphic findings.

7886 OBSTRUCTIVE JAUNDICE CAUSED BY HETEROTOPIC PANCREATIC TISSUE IN THE AMPULLA OF VATER. (Ger.) Hocht, B.; Kuhner, U.; Gay, B.; Arbogast, R. (Chirurgische Universitatsklinik, Josef-Schneider-Str. 2, 8700 Wurzburg, W. Germany). *Z. Kinderchir.* 22(1):79-82; 1977.

Obstructive jaundice due to heterotopic pancreatic tissue in the ampulla of Vater was diagnosed in a 2.75-yr-old girl. Transduodenal sphincterotomy was performed following initial conservative treatment. The patient recovered well. Ten months after surgery, transient signs of obstructive jaundice and pancreatitis appeared; they resolved quickly on conservative treatment. The patient has been sym tom-free for 3.5 yr after surgery.

7887 COURVOISIER'S GALLBLADDER IN CALCULOUS CHOLEDOCHAL OBSTRUCTION: ULTRASOUND AN ^{111}In-PHENOLPHTHALEXON STUDIES. (Eng.) Lin, M. Zatz, L. M.; Kosek, J. C.; Taylor, K. B. (Veteran Admin. Hosp., 3801 Miranda Ave., Palo Alto, CA 94304). *Clin. Nucl. Med.* 2(11):386-388; 1977.

The case of a patient with a distended gallbladde and calculous choledochal obstruction is presente The patient was a 65-yr-old man who had previousl undergone a portacaval shunt operation for decomp sated liver cirrhosis and a Billroth II anastomos for peptic ulcer disease. The patient presented with gastrointestinal bleeding due to an anastomo ulcer, which was oversewn; a bilateral truncal va gotomy was carried out at this time. Following surgery, the patient developed progressive hyperbilirubinemia. Gray scale ultrasonography and biliary scanning using ^{111}In-phenolphthalexon dem onstrated an enlarged gallbladder, suggesting an extrahepatic component in the cholestasis. Analy sis of the ^{111}In excreted in a series of fecal specimens showed a wide variation from high-activ ity dark feces to low-activity pale ones, compati with an intermittent choledochal patency suggesti of calculous obstruction. At autopsy, a 950-g ci rhotic liver (postnecrotic), a dilated common bil duct obstructed by a faceted juxta-ampullary sto and an unobstructed, dilated gallbladder containing stones and showing changes of chronic cholecystitis (mural fibrosis) were found. This case violates Courvoisier's law, which states that an enlarged gallbladder usually indicates a neoplast extrahepatic obstruction.

7888 SPONTANEOUS PERFORATION OF THE COMMON DUCT. (Eng.) Lipinski, J. K.; Gouws, Donald, J. C. (1105 Pandora Ave., 220, Victoria, British Columbia, Canada). *Ann. Surg.* 43(10):65 659; 1977.

Two cases of spontaneous perforation of the comm bile duct are presented, and cases in the literature are reviewed. The first patient, an 86-yr-old woman, presented with acute midabdominal pai distention, and bilious vomiting. There was marked tenderness in the right lower quadrant wi rebound tenderness. Bowel sounds were absent. clinical diagnosis of peritonitis from a rupture viscus was made, and at laparotomy, bile periton was seen. Most of the bile-stained fluid was in the upper abdomen with some inflammatory reactio in the area of the gallbladder and Hartmann's pouch. The gallbladder was full of stones, with a stone impacted in the area of the cystic duct. Dissection was carried out in the area of the triangle of Calot and along the common duct. A 5-mm free perforation of the common bile duct wa found. There was no evidence of stones in the common duct. Following cholecystectomy, a T-tub cholangiogram did not reveal obstruction or comm duct stones. The second patient was an 83-yr-ol woman who presented with anorexia, vomiting, and

dration. Marked right upper quadrant tender-
was present, and rectal examination revealed
acholic stool. Plain abdominal films showed
iple loops of small and large bowel with
ral air-fluid levels. At laparotomy, a large
tity of thick bile-stained fluid was noted.
gallbladder was thin-walled and covered with
rinous exudate but was otherwise normal.
n bile was pouring from a tear in the common
above the junction of the cystic and common
tic ducts. There was no evidence of calculi
eoplasm. A catheter was placed in the common
and a sump drain inserted into the subhepatic
and into the foramen of Winslow and brought
through the abdominal wall. Both patients re-
red following drainage of the duct and the
ounding area. The results of drainage in these
ents and in other patients with common bile duct
oration reported in the literature have been
ifying.

NECROTIZING VASCULITIS OF THE GALLBLADDER
AND THE APPENDIX: SIMILARITY IN THE
HOLOGY OF RHEUMATOID ARTERITIS AND POLYARTERITIS
SA. (Eng.) Fayemi, A. O.; Ali, M.; Braun, E.
oly Name Hosp., Teaneck Rd., Teaneck NJ 07666).
Gastroenterol. 67(6):608-612; 1977.

ases of two patients, one with rheumatoid ar-
is (RA) and the other with polyarteritis no-
(PN), who developed abdominal pain secondary
ecrotizing vasculitis of the gallbladder and
ppendix, resp., are described. The first pa-
was a 61-yr-old man who had been maintained
rticosteroids and butazolidin for RA for 3 yr.
inal pain in this patient was associated with
a and fever. A nonvisualizing gallbladder
oted on p.o. cholecystography, and a diagnosis
ronic cholecystitis was made. Cholecystectomy
erformed. The gallbladder contained viscid
ish bile and 15 strawberry stones. Microscop-
y, the mucosa and submucosa of this organ
d edema and sparse lymphocytic infiltrate. The
of the vessels showed focal fibrinoid necrosis
nfiltration of all layers of the wall by chronic
mmacory cells. Intimal thickening with luminal
wing and, rarely, thrombosis were found. There
ragmentation of the elastic laminas. The patient
3 days after surgery, after developing vomit-
diarrhea, shock, oliguria, and a temperature
.5 C. The second patient was a 48-yr-old man
eveloped acute abdominal pain on the 20th day
spitalization for progressive weakness; he
een treated for joint swelling and pain, which
een diagnosed as gout. The patient was ex-
d surgically for suspected appendicitis, and
dectomy was performed. Microscopically, the
diceal lumen was partially obliterated by fi-
tissue. There were no acute inflammatory
es within the wall. The blood vessels showed
noid necrosis of varying severity. The entire
ness of the vessels was infiltrated by chronic
mmatory cells containing many eosinophils.
esions were of different ages, the wall of
vessels having been replaced by acellular fi-
tissue. Recanalized thrombi were evident
me arteries, and the elastic laminas were
frequently fragmented. These cases illustrate the similarity between the vascular lesions of PN and RA.

GENERAL

7911 ENDOSCOPIC CONTROL OF MASSIVE UPPER GASTROINTESTINAL BLEEDING WITH A TISSUE ADHESIVE (MBR 4197). (Eng.) Martin, T. R.; Onstad, G. R.; Silvis, S. E. (Veterans Admin. Hosp., 54th St. and 48th Ave. South, Minneapolis, MN 55417). *Gastrointest. Endosc.* 24(2):74-76; 1977.

Experience with the use of a tissue adhesive (MBR 4197) in the control of upper gastrointestinal bleeding in nine critically ill patients who were not considered candidates for emergency surgery is presented. The case reports of six patients who were treated successfully by the endoscopic application of MBR 4197 are presented. This treatment was considered to be life-saving in three
tients, one who bled from ulcerated gastric can
and two who bled from esophagitis that was asso
ated with renal failure in one and prostatectom
in the other. These patients required 15, 16,
6 transfusions before treatment and 2, 2, and 0
after treatment, resp. The first patient requi
eight treatments, while the other two required
three. Two additional patients had no further
bleeding from esophagitis or duodenal ulcers bu
died of coexisting hepatic failure, and the las
patient rebled and exsanguinated from esophagea
varices. This uncontrolled study in critically
ill patients indicates that massive bleeding fr

rete and diffuse lesions of the upper gastro-
stinal tract can be controlled by the endos-
c application of tissue adhesives.

VASOACTIVE INTESTINAL PEPTIDE, THE MAJOR MEDIATOR OF THE WDHA (PANCREATIC CHOLERA)
ROME: VALUE OF MEASUREMENT IN DIAGNOSIS AND
TMENT. (Eng.) Bloom, S. R. (Hammersmith Hosp.,
on, England). *Am. J. Dig. Dis.* 23(4):373-376;
.

value of measuring vasoactive intestinal pep-
(VIP) in the diagnosis and treatment of severe
ry diarrhea (pancreatic cholera) syndrome is
ewed. In addition, plasma VIP concentrations
1 healthy subjects, 39 patients with severe
ry diarrhea caused by a VIP-containing tumor,
atients with severe diarrhea and no tumor, and
ther patients are presented. Direct evidence
VIP is the cause of the Verner-Morrison syn-
e and that the presence of an elevated plasma
level in a patient with severe diarrhea strongly
ests the possibility of a tumor was tested in
past in pigs. In this experiment, six of eight
receiving a 10-hr VIP infusion developed se-
watery diarrhea, which stopped after the in-
on was discontinued. One of the major prob-
of research in the area of VIP investigation
been the difficulty of accurate VIP measurement.
d must be collected with the addition of a
eolytic enzyme inhibitor (Aprotinin, 1,000 kal-
ein-inhibiting U/ml blood) and the RBC
dly removed by centrifugation. The plasma
ld be deep frozen within 15 min of venipuncture
stored at -20 C. All samples must be lyophi-
d until their moisture content is below 0.1%
then sealed in vacuum. Normal human plasma
concentrations are below 20 pM. In the patients
ied, it was found that values above about 60
ere indicative of a VIP-producing tumor. The
r in seven patients was outside the pancreas.
concentrations in patients with diarrhea sec-
ry to purgative addiction, thyroid carcinoma,
carcinoma, rectal villus adenoma, and the
inoid syndrome were normal. VIP measurement
seful in monitoring tumor activity during
tment with streptozotocin or steroids.

COMPARISON OF SUCROSE AND GLUCOSE IN THE ORAL ELECTROLYTE THERAPY OF CHOLERA AND
R DIARRHEAS. (Eng.) Palmer, D. L.; Koster, F.
Islam, A. F. M. R.; Rahman, A. S. M. M.; Sack,
. (Veterans Admin. Hosp., Albuquerque, NM 87108).
ngl. J. Med. 297(20):1107-1110; 1977.

effectiveness of sucrose and glucose electro-
solutions as fluid replacement in cholera and
r forms of severe diarrhea was studied in 122
ents, all of whom were over 5 yr of age. The
ents all had a diarrheal volume greater than
/kg/hr during the initial interval of 4 to 6
i.v. fluid rehydration. Sixty-nine patients
received a sucrose electrolyte solution (40
and 53 received a glucose electrolyte solu-
(20 g/1). The sole criterion of the success or failure of p.o. fluid therapy was the ability to maintain adequate hydration without return to i.v. fluids. The total success rate was 86% for the sucrose electrolyte solution and 87% for the glucose electrolyte solution. When the study was restricted to patients with cholera, the outcome with the p.o. fluids was also similar (68% success with sucrose, 78% with glucose). Most failures (13/17) occurred in patients with stool rates over 200 ml/kg/hr during the first 24 hr. Total volumes of each p.o. fluid needed per successful treatment course were essentially identical, averaging 6.0 ± 0.5 1 for sucrose and 5.7 ± 0.7 1 for glucose. In 10 of the 17 failures (7 sucrose and 3 glucose), the same p.o. solution was started again at a later period after i.v. rehydration. There were only two failures this time, one with each solution. The results indicate that sucrose can effectively replace glucose in a p.o. electrolyte solution for severe diarrhea in patients over 5 yr of age.

7914 ALUMINIUM HYDROXIDE IN BILE-SALT DIARRHOEA.
(Eng.) Sali, A.; Murray, W. R.; MacKay, C. (Western Infirmary, Glasgow G11 6NT, Scotland). *Lancet* 2(8047):1051-1053; 1977.

The bile acid-binding property of antacids was investigated in nine patients, and the response of bile salt diarrhea to treatment with aluminum hydroxide was assessed in eight patients with severe choleraic diarrhea. In the first study, the nine peptic ulcer patients received either aluminum hydroxide (15 ml, q.i.d.) or magnesium hydroxide (10 ml, q.i.d.) p.o. for 6 days, and feces were collected over the last 2 days of treatment. The patients were then switched from one antacid to the other, and the fecal collections were repeated. Eleven age-matched controls without gastrointestinal disease received no drug. Fecal bile salt concentrations were significantly higher in patients taking aluminum hydroxide than in controls ($p<0.005$), but concentrations in patients receiving magnesium hydroxide were not significantly different from control values. In the second study, 2-day fecal collections were taken from the eight patients with diarrhea (due to ileal resection for ileal Crohn's disease or to truncal vagotomy and pyloroplasty for chronic duodenal ulceration) before and during treatment with aluminum hydroxide (40-120 ml/day), and the bile salt levels were compared with those in age- and sex-matched controls without gastrointestinal disease. Daily fecal total bile salt output in the patients before treatment was higher than that of the controls ($p<0.0005$). Bile salt output was not significantly affected by treatment with aluminum hydroxide, but analysis of total fecal bile salts does not discriminate between free and bound salts. The mean daily fecal weight decreased from 485 g to 167 g ($p<0.01$) during treatment, and five patients passed formed bowel movements. The frequency of bowel motions during treatment also fell from seven to two per day ($p<0.0005$). No patient has hypophosphatemia after 4 or more months of treatment.

7915 PARACENTESIS AND LAVAGE FOR DIAGNOSIS OF INTESTINAL GANGRENE IN NEONATAL NECROTIZING ENTEROCOLITIS.

(Eng.) Kosloske, A. M.; Lilly, J. R. (Univ. New Mexico Sch. Medicine, 2211 Lomas Blvd., N.E., Albuquerque, NM 87131). *J. Pediatr. Surg.* 13(3):315-320; 1978.

Peritoneal fluid as an index of intestinal gangrene in infants with necrotizing enterocolitis (NEC) was evaluated. Twenty samples of peritoneal fluid were obtained by paracentesis or lavage from 15 infants with nonperforated NEC. A brown color in the peritoneal fluid was noted in all eight patients found to have intestinal gangrene at subsequent operation. Gram stain showed bacteria in six of these patients, and bacterial cultures were confirmatory in all but one. In 12 samples of peritoneal fluid in patients without intestinal gangrene, the fluid was straw-colored or pink, and Gram stain showed no bacteria. The decision to operate on an infant with intestinal gangrene and impending perforation may be aided by analysis of the peritoneal fluid.

7916 OUTBREAK OF NECROTISING ENTEROCOLITIS CAUSED BY Clostridium butyricum.

(Eng.) Howard, F. M.; Bradley, J. M.; Flynn, D. M.; Noone, P.; Szawatkowski, M. (Royal Free Hosp., London NW3 2QG, England). *Lancet* 2(8048): 1099-1102; 1977.

Findings in a cluster of 12 cases of necrotizing enterocolitis that occurred over a 6-week period among 132 babies born in one hospital are presented. In three cases, enterocolitis was severe, requiring surgery. All babies had one or more artificial feeds. Three were breast fed, but all had artificial milk supplements. Seven patients were full-term babies without predisposing conditions, while the premature babies were well at the time of onset of enterocolitis. Only one infant had an Apgar score of less than 5 at birth, none was hypothermic, and only one had respiratory distress (mild). One baby had severe congenital heart disease, and in another, the ductus reopened following surgery for intestinal perforation. None had exchange transfusion; two had umbilical catheters inserted, while four had no nasogastric tubes. Gas-liquid chromatography indicated the presence of *Clostridium butyricum* in blood cultures from 9 of 10 infants tested, and the organism was grown in culture from 7 of these. Acute-phase stool samples from six babies with enterocolitis gave a gas-liquid chromatography pattern compatible with the presence of *C. butyricum*, whereas appropriate controls were negative. In view of previous reports of other *Clostridium* species as pathogenic agents, it is reasonable to suppose that another member of this genus, *C. butyricum*, invaded the gut wall and produced the illness in these cases.

7917 ACRODERMATITIS ENTEROPATHICA IN CHILDHOOD.

(Ger.) Dick, W.; Gladtke, E. (Universitats-Kinderklinik, Josef-Stelzmann-Str. 9, 5000 Koln 41, W. Germany). *Klin. Paediatr.* 189(6):401-403; 1977.

Typical acrodermatitis enteropathica was diagnos in a 5-month-old girl. Oxyquinoline treatment, initiated at the age of 8 months, brought about rapid disappearance of the symptoms, but the ski efflorescences recurred unfailingly whenever the medication was suspended. Impaired vision due t oxyquinoline-induced damage of the optic nerve w seen at the age of 6 yr, which prompted predniso treatment and a prolongation of the intervals between the oxyquinoline treatments. The reduced serum zinc level was normalized by p.o. administ zinc. The cessation of the zinc substitution ca the symptoms to recur. The patient is neurologi ly normal under zinc substitution therapy.

7918 ACETYLCHOLINESTERASE-ACTIVITY IN RECTA MUCOSA OF CHILDREN WITH OBSTIPATION.

(Eng.) Toorman, J.; Bots, G. T. A. M.; Vio, P. A. (Univ. Hosp., Leiden, Netherlands). *Virchows Arch.* [*Pathol. Anat.*] 376(2):159-164; 1977.

Rectal suction biopsy specimens from 46 patients with obstipation were studied histochemically fo acetylcholinesterase activity to determine wheth this measurement could be used in the differenti diagnosis of Hirschsprung's disease. In four ca abundant and coarse acetylcholinesterase-positiv nerve fibers were present in the lamina propria. The diagnosis of Hirschsprung's disease was supported by the clinical course in these patients only. Thirty-two patients with no acetylcholinesterase-positive nerve fibers had clinical features that did not support the diagnosis of Hirs sprung's disease (i.e., ganglion cells present, onset of obstipation after age 1 yr, or spontaneous recovery), as did 10 patients with local ag gregations of fine acetylcholinesterase-positive nerve fibers in the lamina propria. The determination of acetylcholinesterase activity is an easy and safe procedure for the diagnosis of Hirschsprung's disease.

7919 THE EFFECTIVENESS OF ANTIBIOTIC TREATM FOR Salmonella ENTERITIS AND Salmonell EXCRETORS.

(Ger.) Kindler, U.; Schoppe, W. D.; Briese, W. (1. Medizinische Klinik A der Univers tat, Moorenstr. 5, 4000 Dusseldorf, W. Germany). *Dtsch. Med. Wochenschr.* 102(47):1720-1723; 1977.

The effect of single antibiotics (tetracycline, chloramphenicol, ampicillin, penicillin, cotrimo azol) and their combinations (given in the usual dosages) on the duration of *Salmonella* excretion was studied in 122 patients with *Salmonella* enteritis and in 79 asymptomatic *Salmonella* excretors. The average duration of *Salmonella* excretion was 20.4 days in the 97 antibiotic-treated patients with *Salmonella* enteritis versus 15 day in 15 control patients who received symptomatic treatment only. The *Salmonella* excretion ceased in 45/50 asymptomatic excretors treated with anti biotics and in 26/29 untreated control excretors during the first week. The findings indicate th antibiotic treatment does not shorten considerab the duration of *Salmonella* excretion. Therefore, the antibiotic treatment of *Salmonella* infection

ther than typhoid and paratyphoid) should be
mited to systemic forms, while patients with
mplication-free *Salmonella* enteritis as well as
cretors should be treated by purgation.

20 CLINICAL RECOVERY OWING TO TARGET PARI-
ETAL CELL FAILURE IN A PATIENT WITH ZOL-
NGER-ELLISON SYNDROME. (Eng.) Wiersinga, W. M.;
tgat, G. N. (Univ. Hosp., Wilhelmina Gasthuis,
sterdam, Netherlands). *Gastroenterology* 73
):1413-1416; 1977.

e case of a patient with the Zollinger-Ellison
ndrome, in whom spontaneous disappearance of
stric hypersecretion and peptic ulcer disease oc-
rred subsequent to an intercurrent illness caus-
g acute nonspecific inflammation of the gastric
cosal lining, is presented. The patient, a 29-
-old man, had a 3-yr history of recurrent peptic
cer, occasional vomiting, and diarrhea. Upper
strointestinal series and gastroduodenoscopy
monstrated no active ulcer formation or deform-
ies in the duodenal bulb, and gastric biopsies
re normal. The fasting plasma gastrin values
re all elevated. There was no increase in plas-
gastrin after a protein-rich test meal, but the
v. injection of secretin and of ionized calcium
sulted in a dramatic increase of plasma gastrin
th a peak of 2,325 ng/l and 2,330 ng/l, resp.
fore investigations to localize a pancreatic
mor could be undertaken, the patient became
utely ill with general and severe malaise, nausea
d vomiting, and fever. He received only cloraze-
te for nervousness during this time. He gradu-
ly recovered in about 1 week, during which time
stools were produced, which was followed by
full resolution of his previous symptoms. Prior
the intercurrent illness, his basal gastric
id secretion rate was 23.52 mmol/hr, and maximal
id output after pentagastrin stimulation was
.42 mmol/hr. After the illness, the basal
cretion dropped to 0, and the maximal acid
tput was reduced to 1.20 and 0.67 mol/hr,
sp. His basal gastrin level remained high,
did the secretin-stimulated gastrin level.
wever, the meal-stimulated gastrin release
s reduced after the illness. Three months
ter the illness, the gastric mucosa showed severe
flammation with lymphocytes, plasma cells, and
lymorphonuclear leukocytes throughout the gas-
ic mucosa with inflammatory permeation and de-
ruction of the glandular layer. Eight months
ter the illness, evidence of gastritis was still
esent, but the severity of the inflammation was
minished. The dramatic clinical improvement
ter subsiding of the intercurrent illness was
viously linked to pronounced failure of the pari-
al cell mass for acid secretion and not to in-
ction of the gastrinoma, because gastrin hyper-
retion was unchanged.

21 MAGNESIUM SUPPLEMENTATION IN PROTEIN-
CALORIE MALNUTRITION. (Eng.) Nichols,
L.; Alvarado, J.; Hazlewood, C. F.; Viteri, F.
ylor Coll. Medicine, Houston, TX). *Am. J. Clin.*
r. 31(1):176-188; 1978.

GENERAL

Parasitology

7939 *Strongyloides stercoralis* COLITIS: FINDINGS IN FOUR CASES. (Eng.) Drasin, G. F.; Moss, J. P.; Cheng, S. H. (Jewish Hosp., 217 Chestnut St., Louisville, KY 40202). *Radiology* 126(3):619-621; 1978.

The case of a patient with extensive biopsy-proved *Strongyloides stercoralis* colitis is presented, and the radiological findings in this patient and in three others are discussed. The patient was a 61-yr-old man who presented with wheezing and coughing, followed 1 yr later by diarrhea. The first barium enema examination was normal, but another examination carried out after he developed bloody stools showed severe ulcerating colitis with both small and large ulcers, from the cecum to the rectum. Nodularity and a loss of the haustral pattern were noted. Small bowel examination demonstrated typical changes, with fluid, submucosal edema, absence of a mucosal pattern, and slow transit time. Stool specimens for ova and parasites contained larvae of *S. stercoralis*. Ova were present within the submucosa and lamina propria. All three of the other cases were found to have loss of haustration, but ulceration was present in only two. Narrowing was present in the mid-descending colon and distal transverse colon, and stenosis or spasm occurred in the righ colon of another patient. *S. stercoralis* infection was not detected until postmortem examinatio in one patient. Barium enema examinations can help in evaluating the nature and clinical progre of this disease.

Regional Enteritis

7961 ANGIOGRAPHY OF COLONIC CROHN'S DISEASE: THE ZONING SIGN REVISITED. (Eng.) Herlinger, H. (St. James' Univ. Hosp., Leeds, England). *Gastrointest. Radiol.* 2(4):397-400; 1978.

The zoning sign in distinguishing colonic Crohn's disease from ulcerative colitis is described, and the presence or absence of this sign was studied in 40 angiograms. This sign was demonstrated in 50% of the 40 angiograms carried out in patients with colonic Crohn's disease, including six of nine cases of cecal Crohn's disease. When positive, the colon shows a double layer of vascularity, an intensely vascularized inner core (zone A) likely to represent the mucosa/submucosa and an outer cylinder of decreased vascularity (zone B). In 4 of the 40 angiograms, a thin, somewhat interrupted outer layer of vascularity was identified. This was clearly separated from zone A by the seemingly avascular zone B. It can be assumed that this outermost layer represents that of subserosal hyperemia, and it is proposed to refer to it as zone C.

7962 CARCINOEMBRYONIC ANTIGEN (CEA) SERUM LEVELS IN PATIENTS WITH CROHN'S DISEASE IN REGARD TO LOCALIZATION, DURATION AND ACTIVITY OF THE DISEASE. (Ger.) Kruis, W.; Pfaff, G.; Lamerz, R.; Eisenburg, J. (Klinikum Grosshadern der Univ. Munchen, Marchioninistrasse 15, 8 Munich 70, W. Germany). *Fortschr. Med.* 95(47/48):2795-2798; 1977.

The serum levels of carcinoembryonic antigen (CEA) were measured repeatedly in 24 patients with Crohn's disease over a period of up to 35 months. Elevated CEA levels (>3 ng/ml; average, 4.5 ng/ml; maximum, 9 ng/ml) were found in 13 patients. The length of the disease was ≤5 yr in six patients and >5 yr in seven. Both the Crohn's Disease Activity Index (CDAI) and the CEA level were very high in 4 tests, and both parameters were simultaneously low in 10. The incidences of increased CEA levels were 1/3 in patients with Crohn's disease of the ileum, 2/5 patients with Crohn's disease of the colon, and 10/16 patients with Crohn's disease of the ileum and colon. Recurrences were accompanied by increased CEA level in four tests, no increase was seen during recurrence in two tests, and elevation of the CEA level without recurrence was seen in nine tests. The findings show a positive correlation between the extent of the lesion and the CEA serum level but no correlation between the duration of the disease and the CEA level. Good correlation was seen in a few cases between CDAI and the CEA level. It is concluded that the serum CEA level has no diagnostic or prognostic value in Crohn's disease.

7963 LEUCOCYTE ASCORBIC ACID IN CROHN'S DISEASE. (Eng.) Hughes, R. G.; Williams, N. (Bristol Royal Infirmary, Bristol BS2 8HW, England). *Digestion* 17(3):272-274; 1978.

The effects of surgery, diet, and drugs on ascorbic acid status were investigated in 19 patients with Crohn's disease, as spontaneous fistula formation and poor wound healing in this disease may be related to inadequate vitamin C and poor collagen metabolism. The mean leukocyte ascorbic acid (LAA) level in the patients (160.7 ± 19.75 nmol/10^8 WBC) was significantly lower than that in normal age- and sex-matched controls (232.7 ± 40.2 nmol/10^8 WBC, $p<0.01$). There was a positive correlation between dietary ascorbic acid intake and LAA levels ($r=0.302$). No significant difference in LAA levels between those patients who had undergone surgery and those who had not was found. When drug history was reviewed, LAA levels did not differ significantly from the rest of the group. The low LAA levels in patients with Crohn's disease appear to be due to the disease rather than to the effect of drug or operative treatment. Prescribing supplementary ascorbic acid is an appropriate step in correcting this deficiency.

7964 HODGKIN'S DISEASE COMPLICATING CROHN'S COLITIS. (Eng.) Codling, B. W.; Keighley, M. R. B.; Slaney, G. (Queen Elizabeth Hosp., Birmingham, England). *Surgery* 82(5):625-628; 1977.

A case of Hodgkin's disease involving an area of Crohn's colitis in a 35-yr-old patient with a 20-yr history of inflammatory bowel disease is described. The patient presented with weight loss, abdominal pain, bloody diarrhea, and night sweats. The mucosa of the terminal ileum and colon showed extensive fissuring, a cobblestone pattern, and transmural thickening. The terminal 18 cm of resected colon was diffusely infiltrated by a firm, white tumor tissue. The attached lymph nodes were enlarged with a uniform, pale, cut surface. Parrafin sections of the resected tissue showed prominent lymphoid tissue with a diffuse increase in eosinophils and fibrous tissue. The mucosa of the small intestine also showed large numbers of Paneth cells and lymphocytes, but there was no evidence of small intestinal involvement by Crohn's disease or Hodgkin's lymphoma. The proximal colon showed features typical of Crohn's disease, but there was no evidence of tumor involvement. The wall of the distal colon showed extensive mucosal ulceration, an acute and chronic inflammatory cell reaction, and diffuse tumor infiltration (histiocytes, plasma cells, lymphocytes, a few eosinophils), and the lymph nodes attached to the specimen showed replacement by Hodgkin's tissue similar to that in the main tumor mass. The diagnosis was Hodgkin's disease of the mixed cellularity type After radiotherapy, quadruple chemotherapy, and an additional laparotomy for an abdominal abscess, the patient has gained weight, has no evidence of tumor recurrence, and is well despite hepatic in-

lvement from the original tumor. The simultan-
us occurrence of these two entities may be co-
cidental, or there may be a true association be-
een Crohn's disease and lymphoma. If so, it is
kely that altered immune mechanisms play a role
the pathogenesis of the condition.

65 A FAMILIAL PATTERN IN INFLAMMATORY DISEASE
OF THE BOWEL (CROHN'S DISEASE AND ULCERA-
VE COLITIS). (Eng.) Dassel, P. M. (Ferguson-
oste-Ferguson Hosp., 72 Sheldon Blvd. S.E., Grand
pids, MI 49502). *Dis. Colon Rectum* 20(8):669-671;
77.

elve families in which two or more members had in-
ammatory bowel disease are reported. The families
re of Caucasian, non-Jewish descent. The greatest
cidence of inflammatory bowel disease occurred in
milies 1 and 2, in which three sisters and a male
usin in a family of 10, and two brothers, one son,
d two daughters in a family of 13, resp., were af-
cted by Crohn's disease. Another family was unus-
l in that the husband and wife had Crohn's disease
d ulcerative colitis, resp., and one of two child-
n had ulcerative colitis. There were a total of
cases of Crohn's disease and 7 of ulcerative coli-
s. The most common association in familial bowel
seases was in siblings, and then in parent-child
lationships.
